1 History timeline

This is 1.4a of 2020/02/19.

Please refer [CHANGES.html](#) for a (much more) detailed history.

Internet: <http://mirrors.ctan.org/macros/generic/xint/CHANGES.html>

- Release 1.4a of 2020/02/19: fixes 1.4 known bugs. Improves documentation.
- Release 1.4 of 2020/01/31: `xintexpr` overhaul to use `\expanded` based expansion control. Many new features, in particular support for input and output of nested structures. Breaking changes, main ones being the (provisionary) drop of `x*[a, b,...]`, `x+[a, b,...]` et al. syntax and the requirement of `\expanded` primitive (currently required only by `xintexpr`).
- Release 1.3f of 2019/09/10: starred variant `\xintDigits*`.
- Release 1.3e of 2019/04/05: packages `xinttrig`, `xintlog`; `\xintdefefunc` ``non-protected'' variant of `\xintdeffunc` (at 1.4 the two got merged and `\xintdefefunc` became a deprecated alias for `\xintdeffunc`). Indices removed from `sourcexint.pdf`.
- Release 1.3d of 2019/01/06: fix of 1.2p bug for division with a zero dividend and a one-digit divisor, `\xinteval` et al. wrappers, `gcd()` and `lcm()` work with fractions.
- Release 1.3c of 2018/06/17: documentation better hyperlinked, indices added to `sourcexint.pdf`. Colon in `:=` now optional for `\xintdefvar` and `\xintdeffunc`.
- Release 1.3b of 2018/05/18: randomness related additions (still WIP).
- Release 1.3a of 2018/03/07: efficiency fix of the mechanism for recursive functions.
- Release 1.3 of 2018/03/01: addition and subtraction use systematically least common multiple of denominators. Extensive under-the-hood refactoring of `\xintNewExpr` and `\xintdeffunc` which now allow recursive definitions. Removal of 1.2o deprecated macros.
- Release 1.2q of 2018/02/06: fix of 1.2l subtraction bug in special situation; tacit multiplication extended to cases such as `10!20!30!`.
- Release 1.2p of 2017/12/05: maps `//` and `/:` to the floored, not truncated, division. Simultaneous assignments possible with `\xintdefvar`. Efficiency improvements in `xinttools`.
- Release 1.2o of 2017/08/29: massive deprecations of those macros from `xintcore` and `xint` which filtered their arguments via `\xintNum`.
- Release 1.2n of 2017/08/06: improvements of `xintbinhex`.
- Release 1.2m of 2017/07/31: rewrite of `xintbinhex` in the style of the 1.2 techniques.
- Release 1.2l of 2017/07/26: under the hood efficiency improvements in the style of the 1.2 techniques; subtraction refactored. Compatibility of most `xintfrac` macros with arguments using non-delimited `\the\numexpr` or `\the\mathcode` etc...
- Release 1.2i of 2016/12/13: under the hood efficiency improvements in the style of the 1.2 techniques.
- Release 1.2 of 2015/10/10: complete refactoring of the core arithmetic macros and faster `\xintexpr` parser.
- Release 1.1 of 2014/10/28: extensive changes in `xintexpr`. Addition and subtraction do not multiply denominators blindly but sometimes produce smaller ones. Also with that release, packages `xintkernel` and `xintcore` got extracted from `xinttools` and `xint`.

TOC, xintkernel, xinttools, xintcore, xint, xintbinhex, xintgcd, xintfrac, xintseries, xintcfrac, xintexpr, xinttrig, xintlog

- Release 1.09g of 2013/11/22: the `xinttools` package is extracted from `xint`; addition of `\xintloop` and `\xintiloop`.
- Release 1.09c of 2013/10/09: `\xintFor`, `\xintNewNumExpr` (ancestor of `\xintNewExpr`/`\xintdeffunc` mechanism).
- Release 1.09a of 2013/09/24: support for functions by `xintexpr`.
- Release 1.08 of 2013/06/07: the `xintbinhex` package.
- Release 1.07 of 2013/05/25: support for floating point numbers added to `xintfrac` and first release of the `xintexpr` package (provided `\xintexpr` and `\xintfloatexpr`).
- Release 1.04 of 2013/04/25: the `xintcfrac` package.
- Release 1.03 of 2013/04/14: the `xintfrac` and `xintseries` packages.
- Release 1.0 of 2013/03/28: initial release of the `xint` and `xintgcd` packages.

Some parts of the code still date back to the initial release, and at that time I was learning my trade in expandable TeX macro programming. At some point in the future, I will have to re-examine the older parts of the code.

Warning: pay attention when looking at the code to the catcode configuration as found in `\XINT_setcatcodes`. Additional temporary configuration is used at some locations. For example `!` is of catcode letter in `xintexpr` and there are locations with funny catcodes e.g. using some letters with the math shift catcode.

2 Package [xintkernel](#) implementation

.1	Catcodes, ε - \TeX and reload detection	4	.12	\backslash xintReverseOrder	11
.1.1	\backslash XINT_setcatcodes, \backslash XINT_storecatcodes, \backslash XINT_restorecatcodes_endininput	5	.13	\backslash xintLength	11
.2	Package identification	7	.14	\backslash xintLastItem	12

			.24	(WIP) Expandable error message	19

This package provides the common minimal code base for loading management and catcode control and also a few programming utilities. With 1.2 a few more helper macros and all \backslash chardef's have been moved here. The package is loaded by both [xintcore.sty](#) and [xinttools.sty](#) hence by all other packages.

1.1. separated package.

1.2i. \backslash xintreplicate, \backslash xintgobble, \backslash xintLengthUpTo and \backslash xintLastItem, and faster \backslash xintLength.

1.3b. \backslash xintUniformDeviate.

1.4 (2020/01/11). \backslash xintReplicate, \backslash xintGobble, \backslash xintLastOne, \backslash xintFirstOne.

2.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

2.2 Package identification

Inspired from HEIKO OBERDIEK's packages. Modified in 1.09b to allow re-use in the other modules. Also I assume now that if `\ProvidesPackage` exists it then does define `\ver@<pkgname>.sty`, code of HO for some reason escaping me (compatibility with LaTeX 2.09 or other things ??) seems to set extra precautions.

1.09c uses e- \TeX `\ifdefined`.

```
124 \ifdefined\ProvidesPackage
125   \let\XINT_providespackage\relax
126 \else
127   \def\XINT_providespackage #1#2[#3]%
128     {\immediate\write-1{Package: #2 #3}%
129      \expandafter\xdef\csname ver@#2.sty\endcsname{#3}}%
130 \fi
131 \XINT_providespackage
132 \ProvidesPackage {xintkernel}%
133 [2020/02/19 v1.4a Paraphernalia for the xint packages (JFB)]%
```

2.3 Constants

```

165 \fi

```

2.5 Token management utilities

1.3b. `\xint_gobandstop_...` macros because this is handy for `\xintRandomDigits`. **1.3g** forces `\empty` and `\space` to have their standard meanings, rather than simply alerting user in the (theoretical) case they don't that nothing will work. If some **TeX** user has `\renewcommanded` them they will be long and this will trigger `xint` redefinitions and warnings.

```

2.8 `\xint_bye`, `\xint_Bye`

1.09. `\xint_bye`

1.21. `\xint_Bye` for `\xintDSRr` and `\xintRound`. Also `\xint_stop_afterbye`.

```

240 \long\def\xint_bye #1\xint_bye {}%
241 \long\def\xint_Bye #1\xint_bye {}%
242 \long\def\xint_stop_afterbye #1\xint_bye { }%

```

2.9 `\xintdothis`, `\xintorthat`

1.1.

1.2. names without underscores.

To be used this way:

```

\if..\xint_dothis{..}\fi
\if..\xint_dothis{..}\fi

```

```
\if..\xint_dothis{..}\fi
...more such...
\xint_orthat{...}
```

Ancient testing indicated it is more efficient to list first the more improbable clauses.

```
243 \long\def\xint_dothis #1#2\xint_orthat #3{\fi #1}% 1.1
244 \let\xint_orthat \xint_firstofone
245 \long\def\xintdothis #1#2\xintorthat #3{\fi #1}%
246 \let\xintorthat \xint_firstofone
```

2.10 \xint_zapspaces

1.1.

This little (quite fragile in the normal sense i.e. non robust in the normal sense of programming lingua) utility zaps leading, intermediate, trailing, spaces in completely expanding context (`\e def, \csname...\endcsname`).

Usage: `\xint_zapspaces foo<space>\xint_gobble_i`

Explanation: if there are leading spaces, then the first #1 will be empty, and the first #2 being undelimited will be stripped from all the remaining leading spaces, if there was more than one to start with. Of course brace-stripping may occur. And this iterates: each time a #2 is removed, either we then have spaces and next #1 will be empty, or we have no spaces and #1 will end at the first space. Ultimately #2 will be `\xint_gobble_i`.

The `\zap@spaces` of LaTeX2e handles unexpectedly things such as

```
\zap@spaces 1 {22} 3 4 \@empty
```

(spaces are not all removed). This does not happen with `\xint_zapspaces`.

But for example `\foo{aa} {bb} {cc}` where `\foo` is a macro with three non-delimited arguments breaks expansion, as expansion of `\foo` will happen with `\xint_zapspaces` still around, and even if it wasn't it would have stripped the braces around `{bb}`, certainly breaking other things.

Despite such obvious shortcomings it is enough for our purposes. It is currently used by `xintexpr` at various locations e.g. cleaning up optional argument of `\xintiexpr` and `\xintfloatexpr`; maybe in future internal usage will drop this in favour of a more robust utility.

1.2e. \xint_zapspaces_o.

1.2i. made \long.

ATTENTION THAT `xinttools` HAS AN WHICH SHOULD NOT GET CONFUSED WITH THIS ONE

```
247 \long\def\xint_zapspaces #1 #2{\#1#2\xint_zapspaces }% 1.1
248 \long\def\xint_zapspaces_o #1{\expandafter\xint_zapspaces#1 \xint_gobble_i}%
```

2.11 \odef, \oodef, \fdef

May be prefixed with `\global`. No parameter text.

257 \ifdef\fdef\else\let\fdef\xintfdef\fi
```

2.12 \xintReverseOrder

1.0. does not expand its argument. The whole of xint codebase now contains only two calls to `\XINT_rord_main` (in `xintgcd`).

Attention: removes brace pairs (and swallows spaces).

For digit tokens a faster reverse macro is provided by (1.2) `\xintReverseDigits` in `xint`.

For comma separated items, 1.2g has `\xintCSVReverse` in `xinttools`.

```
258 \def\xintReverseOrder {\romannumeral0\xintreverseorder }%
259 \long\def\xintreverseorder #1%

276 }}\XINT_rord_cleanup { }%
```

2.13 \xintLength

1.0. does not expand its argument. See `\xintNthElt{0}` from `xinttools` which f-expands its argument.

1.2g. added `\xintCSVLength` to `xinttools`.

1.2i. rewrote this venerable macro. New code about 40% faster across all lengths. Syntax with `\r` `\romannumeral0` adds some slight (negligible) overhead; it is done to fit some general principles of structure of the xint package macros but maybe at some point I should drop it. And in fact it is often called directly via the `\numexpr` access point. (bad coding...)

```
277 \def\xintLength {\romannumeral0\xintlength }%
278 \def\xintlength #1{%

323 \def\XINT_firstitem_end\xint:{ }%
```

2.16 \xintLastOne

As `xintexpr` 1.4 uses `{c1}{c2}....{cN}` storage when gathering comma separated values we need to not handle identically an empty list and a list with an empty item (as the above allows hierarchical structures). But `\xintLastItem` removed one level of brace pair so it is inadequate for the `last()` function.

By the way it is logical to interpret «item» as meaning `{cj}` inclusive of the braces; but `xint` user manual was not written in this spirit. And thus `\xintLastItem` did brace stripping, thus we

need another name for maintaining backwards compatibility (although the cardinality of users is small).

The `\xint:` token must not be found (visible) among the item contents.

```

```

2.17 `\xintFirstOne`

For `xintexpr` 1.4 too. Jan 3, 2020.

This is an experimental macro, don't use it. If input is nil (empty set) it expands to nil, if not it fetches first item and brace it. Fetching will have stripped one brace pair if item was braced to start with, which is the case in non-symbolic `xintexpr` data objects.

I have not given much thought to this (make it shorter, allow all tokens, (we could first test if empty via combination with `\detokenize`), etc...) as I need to get `xint` 1.4 out soon. So in particular attention that the macro assumes the `\xint:` token is absent from first item of input.

```

347 \def\xintFirstOne {\romannumeral0\xintfirstone }%
348 \long\def\xintfirstone #1{\XINT_firstone #1{\xint:\XINT_firstone_empty}\xint:}%

2.19 \xintreplicate, \xintReplicate

1.2i.

This is cloned from LaTeX3's `\prg_replicate:nn`, see Joseph's post at

<http://tex.stackexchange.com/questions/16189/repeat-command-n-times>

I posted there an alternative not using the chained `\csname`'s but it is a bit less efficient (except perhaps for thousands of repetitions). The code in Joseph's post does `abs(#1)` replications when input `#1` is negative and then activates an error triggering macro; here we simply do nothing when `#1` is negative.

Usage: `\romannumeral\xintreplicate{N}{stuff}`

When `N` is already explicit digits (even `N=0`, but non-negative) one can call the macro as

`\romannumeral\XINT_rep N\endcsname {foo}`

to skip the `\numexpr`.

1.4 (2020/01/11). Added `\xintReplicate` ! The reason I did not before is that the prevailing habits in `xint` source code was to trigger with `\romannumeral0` not `\romannumeral` which is the lowercased named macros. Thus adding the camelcase one creates a couple `\xintReplicate/\xintreplicate` not obeying the general mold.

```

3.4 \xintRevWithBraces

New with 1.06. Makes the expansion of its argument and then reverses the resulting tokens or braced tokens, adding a pair of braces to each (thus, maintaining it when it was already there.) The reason for \xint:, here and in other locations, is in case #1 expands to nothing, the \romannumeral-`0 must be stopped

```

89 }\XINT_revwbr_finish_c{ }%

```

3.5 \xintZapFirstSpaces

1.09f, written [2013/11/01]. Modified (2014/10/21) for release 1.1 to correct the bug in case of an empty argument, or argument containing only spaces, which had been forgotten in first version. New version is simpler than the initial one. This macro does NOT expand its argument.

```

90 \def\xintZapFirstSpaces {\romannumeral0\xintzapfirstspaces }%
91 \def\xintzapfirstspaces#1{\long
92 \def\xintzapfirstspaces ##1{\XINT_zapbsp_a #1##1\xint:#1#1\xint:}%
93 }\xintzapfirstspaces{ }%

```

If the original #1 started with a space, the grabbed #1 is empty. Thus `_again?` will see `#1=\xint_bye`, and hand over control to `_again` which will loop back into `\XINT_zapbsp_a`, with one initial space less. If the original #1 did not start with a space, or was empty, then the #1 below will be a `<sptoken>`, then an extract of the original #1, not empty and not starting with a space, which contains what was up to the first `<sp><sp>` present in original #1, or, if none preexisted, `<sptoken>` and all of #1 (possibly empty) plus an ending `\xint:`. The added initial space will stop later the `\romannumeral0`. No brace stripping is possible. Control is handed over to `\XINT_zapbsp_b` which strips out the ending `\xint:<sp><sp>\xint:`:

```
94 \def\XINT_zapbsp_a#1{\long\def\XINT_zapbsp_a ##1#1#1{%
95   \XINT_zapbsp_again?##1\xint_bye}\XINT_zapbsp_b ##1#1#1}%
96 }\XINT_zapbsp_a{ }%
97 \long\def\XINT_zapbsp_again? #1{\xint_bye #1\XINT_zapbsp_again }%
98 \xint_firstofone{\def\XINT_zapbsp_again\XINT_zapbsp_b} {\XINT_zapbsp_a }%
99 \long\def\XINT_zapbsp_b #1\xint:#2\xint:{#1}%
```

3.6 `\xintZapLastSpaces`

1.09f, written [2013/11/01].

```
100 \def\xintZapLastSpaces {\romannumeral0\xintzaplastspaces }%
101 \def\xintzaplastspaces#1{\long
102 \def\xintzaplastspaces ##1{\XINT_zapesp_a {} \empty##1#1\xint_bye\xint:{}%
103 }\xintzaplastspaces{ }%
```

The `\empty` from `\xintzaplastspaces` is to prevent brace removal in the #2 below. The `\expandafter` chain removes it.

```
104 \xint_firstofone {\long\def\XINT_zapesp_a #1#2 } %<- second space here
105   {\expandafter\XINT_zapesp_b\expandafter{#2}{#1}}%
```

Notice again an `\empty` added here. This is in preparation for possibly looping back to `\XINT_zapesp_a`. If the initial #1 had no `<sp><sp>`, the stuff however will not loop, because #3 will already be `<some spaces>\xint_bye`. Notice that this macro fetches all way to the ending `\xint:`. This looks not very efficient, but how often do we have to strip ending spaces from something which also has inner stretches of `_multiple_` space tokens ?;-).

```
106 \long\def\XINT_zapesp_b #1#2#3\xint:%
107   {\XINT_zapesp_end? #3\XINT_zapesp_e {#2#1}\empty #3\xint:{}%
```

When we have been over all possible `<sp><sp>` things, we reach the ending space tokens, and #3 will be a bunch of spaces (possibly none) followed by `\xint_bye`. So the #1 in `_end?` will be `\xint_bye`. In all other cases #1 can not be `\xint_bye` (assuming naturally this token does not arise in original input), hence control falls back to `\XINT_zapesp_e` which will loop back to `\XINT_zapesp_a`.

```
108 \long\def\XINT_zapesp_end? #1{\xint_bye #1\XINT_zapesp_end }%
```

We are done. The #1 here has accumulated all the previous material, and is stripped of its ending spaces, if any.

```
109 \long\def\XINT_zapesp_end\XINT_zapesp_e #1#2\xint:{ #1}%

3.9 \xintCSVtoList, \xintCSVtoListNonStripped

\xintCSVtoList transforms a,b,...,z into {a}{b}...{z}. The comma separated list may be a macro which is first f-expanded. First included in release 1.06. Here, use of \Z (and \R) perfectly safe.

[2013/11/02]: Starting with 1.09f, automatically filters items with \xintZapSpacesB to strip away all spaces around commas, and spaces at the start and end of the list. The original is kept as \xintCSVtoListNonStripped, and is faster. But ... it doesn't strip spaces.

ATTENTION: if the input is empty the output contains one item (empty, of course). This means an \xintFor loop always executes at least once the iteration, contrarily to \xintFor*.

3.10 \xintListWithSep

1.04. `\xintListWithSep {\sep}{\{a\}{b}\dots\{z\}}` returns a `\sep b \sep\sep z`. It f-expands its second argument. The 'sep' may be `\par`'s: the macro `\xintlistwithsep` etc... are all declared long. 'sep' does not have to be a single token. It is not expanded. The "list" argument may be empty.

`\xintListWithSepNoExpand` does not f-expand its second argument.

This venerable macro from 1.04 remained unchanged for a long time and was finally refactored at 1.2p for increased speed. Tests done with a list of identical `\x` items and a sep of `\z` demonstrated a speed increase of about:

- 3x for 30 items,
- 4.5x for 100 items,
- 7.5x--8x for 1000 items.

```

3.11 \xintNthElt

First included in release 1.06. Last refactored in 1.2j.

`\xintNthElt {i}{List}` returns the i th item from List (one pair of braces removed). The list is first f-expanded. The `\xintNthEltNoExpand` does no expansion of its second argument. Both variants expand i inside `\numexpr`.

With $i = 0$, the number of items is returned using `\xintLength` but with the List argument f-expanded first.

Negative values return the $|i|$ th element from the end.

When i is out of range, an empty value is returned.

```

3.13 \xintKeep

First included in release 1.09m.

\xintKeep{i}{L} f-expands its second argument L. It then grabs the first i items from L and discards the rest.

ATTENTION: **each such kept item is returned inside a brace pair** Use \xintKeepUnbraced to avoid that.

For i equal or larger to the number N of items in (expanded) L, the full L is returned (with braced items). For i=0, the macro returns an empty output. For i<0, the macro discards the first N-|i| items. No brace pairs added to the remaining items. For i is less or equal to -N, the full L is returned (with no braces added.)

\xintKeepNoExpand does not expand the L argument.

Prior to 1.2i the code proceeded along a loop with no pre-computation of the length of L, for the i>0 case. The faster 1.2i version takes advantage of novel \xintLengthUpTo from xintkernel.sty.

3.14 \xintKeepUnbraced

1.2a. Same as `\xintKeep` but will *not* add (or maintain) brace pairs around the kept items when `length(L)>i>0`.

The name may cause a mis-understanding: for `i<0`, (i.e. keeping only trailing items), there is no brace removal at all happening.

Modified for 1.2i like `\xintKeep`.

3.15 \xintTrim

First included in release 1.09m.

`\xintTrim{i}{L}` f-expands its second argument L. It then removes the first i items from L and keeps the rest. For i equal or larger to the number N of items in (expanded) L, the macro returns an empty output. For i=0, the original (expanded) L is returned. For i<0, the macro proceeds from

the tail. It thus removes the last $|i|$ items, i.e. it keeps the first $N - |i|$ items. For $|i| \geq N$, the empty list is returned.

`\xintTrimNoExpand` does not expand the L argument.

Speed improvements with 1.2i for $i < 0$ branch (which hands over to `\xintKeep`). Speed improvements with 1.2j for $i > 0$ branch which gobbles items nine by nine despite not knowing in advance if it will go too far.

3.18 \xintApply:x (not public)

Done for 1.4, 2020/01/27. For usage in the NumPy-like slicing routines.

Supposed to expand in an \expanded context, does not need to do any expansion of its second argument.

Uses techniques I had developed for 1.2i/1.2j Keep, Trim, Length, LastItem like macros, and I should revamp venerable \xintApply probably too. But the latter f-expandability (if it does not have \expanded at disposal) complicates significantly matters as it has to store material and release at very end.

Here it is simpler and I am doing it quickly as I really want to release 1.4. The \xint: token should not be located in looped over items. I could use something more exotic like the null char with catcode 3...

Could be however that picking one by one would be better for small number of items.

And anyhow for small number of items gain with respect to \xintApply is little if any (might even be a loss).

```

3.19 \xintApplyUnbraced

`\xintApplyUnbraced {\macro}{a}{b}...{z}` returns `\macro{a}... \macro{z}` where each instance of `\macro` is f-expanded using `\romannumeral`0`. The second argument may be a macro as it is itself also f-expanded. No braces are added: this allows for example a non-expandable `\def` in `\macro`, without having to do `\gdef`. Introduced with release 1.06b.

```

3.25 \xintApplyInline

1.09a: `\xintApplyInline\macro{{a}{b}...{z}}` has the same effect as executing `\macro{a}` and then applying again `\xintApplyInline` to the shortened list `{b}...{z}` until nothing is left. This is a non-expandable command which will result in quicker code than using `\xintApplyUnbraced`. It f-expands its second (list) argument first, which may thus be encapsulated in a macro.

Rewritten in 1.09c. Nota bene: uses catcode 3 Z as privated list terminator.

```

3.26 `\xintFor`, `\xintFor*`, `\xintBreakFor`, `\xintBreakForAndDo`

1.09c [2013/10/09]: a new kind of loop which uses macro parameters #1, #2, #3, #4 rather than macros; while not expandable it survives executing code closing groups, like what happens in an alignment with the & character. When inserted in a macro for later use, the # character must be doubled.

The non-star variant works on a csv list, which it expands once, the star variant works on a token list, which it (repeatedly) f-expands.

1.09e adds `\XINT_forever` with `\xintintegers`, `\xintdimensions`, `\xintrationals` and `\xintBreakFor`, `\xintBreakForAndDo`, `\xintifForFirst`, `\xintifForLast`. On this occasion `\xint_firstoftwo` and `\xint_secondeftwo` are made long.

1.09f: rewrites large parts of `\xintFor` code in order to filter the comma separated list via `\xintCSVtoList` which gets rid of spaces. The #1 in `\XINT_for_forever?` has an initial space token which serves two purposes: preventing brace stripping, and stopping the expansion made by `\xintcsvtolist`. If the `\XINT_forever` branch is taken, the added space will not be a problem there.

1.09f rewrites (2013/11/03) the code which now allows all macro parameters from #1 to #9 in `\xintFor`, `\xintFor*`, and `\XINT_forever`. 1.2i: slightly more robust `\xintifForFirst/Last` in case of nesting.

3.27 \XINT_forever, \xintintegers, \xintdimensions, \xintrationals

New with 1.09e. But this used inadvertently `\xintiadd/\xintimul` which have the unnecessary `\xintnum` overhead. Changed in 1.09f to use `\xintiiadd/\xintiimul` which do not have this overhead. Also 1.09f uses `\xintZapSpacesB` for the `\xintrationals` case to get rid of leading and ending spaces in the #4 and #5 delimited parameters of `\XINT_forever_opt_a` (for `\xintintegers` and `\xintdimensions` this is not necessary, due to the use of `\numexpr` resp. `\dimexpr` in `\XINT_?expr_Ua`, resp. `\XINT_?expr_Da`).

3.28 \xintForpair, \xintForthree, \xintForfour

1.09c.

[2013/11/02] 1.09f \xintForpair delegate to \xintCSVtoList and its \xintZapSpacesB the handling of spaces. Does not share code with \xintFor anymore.

[2013/11/03] 1.09f: \xintForpair extended to accept #1#2, #2#3 etc... up to #8#9, \xintForthree, #1#2#3 up to #7#8#9, \xintForfour id.

1.2i: slightly more robust \xintifForFirst/Last in case of nesting.

3.29 \xintAssign, \xintAssignArray, \xintDigitsOf

\xintAssign {a}{b}..{z}\to\A\B... \Z resp. \xintAssignArray {a}{b}..{z}\to\U.
 \xintDigitsOf=\xintAssignArray.

1.1c 2015/09/12 has (belatedly) corrected some "features" of \xintAssign which didn't like the case of a space right before the "\to", or the case with the first token not an opening brace and the subsequent material containing brace groups. The new code handles gracefully these situations.

3.30 CSV (non user documented) variants of Length, Keep, Trim, NthElt, Reverse

These routines are for use by `\xintListSel:x:csv` and `\xintListSel:f:csv` from [xintexpr](#), and also for the `reversed` and `len` functions. Refactored for [1.2j](#) release, following [1.2i](#) updates to `\xintKeep`, `\xintTrim`, ...

These macros will remain undocumented in the user manual:

-- they exist primarily for internal use by the [xintexpr](#) parsers, hence don't have to be general purpose; for example, they a priori need to handle only catcode 12 tokens (not true in `\xintNewExpr`, though) hence they are not really worried about controlling brace stripping (nevertheless [1.2j](#) has paid some secondary attention to it, see below.) They are not worried about normalizing leading spaces either, because none will be encountered when the macros are used as auxiliaries

to the expression parsers.

-- crucial design elements may change in future:

1. whether the handled lists must have or not have a final comma. Currently, the model is the one of comma separated lists with **no** final comma. But this means that there can not be a distinction of principle between a truly empty list and a list which contains one item which turns out to be empty. More importantly it makes the coding more complicated as it is needed to distinguish the empty list from the single-item list, both lacking commas.

For the internal use of [xintexpr](#), it would be ok to require all list items to be terminated by a comma, and this would bring quite some simplifications here, but as initially I started with non-terminated lists, I have left it this way in the [1.2j](#) refactoring.

2. the way to represent the empty list. I was tempted for matter of optimization and synchronization with [xintexpr](#) context to require the empty list to be always represented by a space token and to not let the macros admit a completely empty input. But there were complications so for the time being [1.2j](#) does accept truly empty output (it is not distinguished from an input equal to a space token) and produces empty output for empty list. This means that the status of the «nil» object for the [xintexpr](#) parsers is not completely clarified (currently it is represented by a space token).

The original Python slicing code in [xintexpr 1.1](#) used `\xintCSVtoList` and `\xintListWithSep{,}` to convert back and forth to token lists and apply `\xintKeep`/`\xintTrim`. Release [1.2g](#) switched to devoted f-expandable macros added to [xinttools](#). Release [1.2j](#) refactored all these macros as a follow-up to [1.2i](#) improvements to `\xintKeep`/`\xintTrim`. They were made `\long` on this occasion and auxiliary `\xintLengthUpTo:f:csv` was added.

Leading spaces in items are currently maintained as is by the [1.2j](#) macros, even by `\xintNthEltP:y:f:csv`, with the exception of the first item, as the list is f-expanded. Perhaps `\xintNthEltPy:f:csv` should remove a leading space if present in the picked item; anyway, there are no spaces for the lists handled internally by the Python slicer of [xintexpr](#), except the «nil» object currently represented by exactly one space.

Kept items (with no leading spaces; but first item special as it will have lost a leading space due to f-expansion) will lose a brace pair under `\xintKeep:f:csv` if the first argument was positive and strictly less than the length of the list. This differs of course from `\xintKeep` (which always braces items it outputs when used with positive first argument) and also from `\xintKeepUnbraced` in the case when the whole list is kept. Actually the case of singleton list is special, and brace removal will happen then.

This behaviour was otherwise for releases earlier than [1.2j](#) and may change again.

Directly usable names are provided, but these macros (and the behaviour as described above) are to be considered *unstable* for the time being.

3.30.1 `\xintLength:f:csv`

[1.2g](#). Redone for [1.2j](#). Contrarily to `\xintLength` from `xintkernel.sty`, this one expands its argument.

```

3.30.3 `\xintKeep:f:csv`

1.2g 2016/03/17. Redone for 1.2j with use of `\xintLengthUpTo:f:csv`. Same code skeleton as `\xintKeep` but handling comma separated but non terminated lists has complications. The `\xintKeep` in case of a negative #1 uses `\xintgobble`, we don't have that for comma delimited items, hence we do a special loop here (this style of loop is surely competitive with `xintgobble` for a few dozens items and even more). The loop knows before starting that it will not go too far.

```

This strange thing is in case the picked item was the last one, hence there was an ending `\xint:` (we could not put a comma earlier for matters of not confusing empty list with a singleton list), and we do this here to activate brace-stripping of item as all other items may be brace-stripped if picked. This is done for coherence. Of course, in the context of the `xintexpr.sty` parsers, there are no braces in list items...

```

3.30.6 `\xintReverse:f:csv`

1.2g. Contrarily to `\xintReverseOrder` from `xintkernel.sty`, this one expands its argument. Handles empty list too. 2016/03/17. Made `\long` for 1.2j.

```

1517 \def\xintReverse:f:csv {\romannumerical0\xintreverse:f:csv }%
1518 \long\def\xintreverse:f:csv #1%
1519 {%
1520     \expandafter\XINT_reverse:f:csv_loop

```

3.30.10 Public names for the undocumented csv macros: `\xintCSVLength`, `\xintCSVKeep`,
`\xintCSVKeepx`, `\xintCSVTrim`, `\xintCSVNthEltPy`, `\xintCSVReverse`, `\xintCSVFirstItem`,
`\xintCSVLastItem`

Completely unstable macros: currently they expand the list argument and want no final comma. But for matters of *xintexpr.sty* I could as well decide to require a final comma, and then I could simplify implementation but of course this would break the macros if used with current functionalities.

```

Got split off from `xint` with release 1.1.

The core arithmetic routines have been entirely rewritten for release 1.2. The 1.2i and 1.2l brought again some improvements.

The commenting continues (2020/02/19) to be very sparse: actually it got worse than ever with release 1.2. I will possibly add comments at a later date, but for the time being the new routines are not commented at all.

1.3 removes all macros which were deprecated at 1.2o.

4.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

4.3 (WIP!) Error conditions and exceptions

As per the Mike Cowlishaw/IBM's General Decimal Arithmetic Specification
<http://speleotrove.com/decimal/decarith.html>
and the Python3 implementation in its Decimal module.
Clamped, ConversionSyntax, DivisionByZero, DivisionImpossible, DivisionUndefined, Inexact,
InsufficientStorage, InvalidContext, InvalidOperation, Overflow, Inexact, Rounded, Subnormal,
Underflow.

X3.274 rajoute LostDigits
Python rajoute FloatOperation (et n'inclut pas InsufficientStorage)
quote de decarith.pdf: The Clamped, Inexact, Rounded, and Subnormal conditions can coincide
with each other or with other conditions. In these cases then any trap enabled for another condition
takes precedence over (is handled before) all of these, any Subnormal trap takes precedence
over Inexact, any Inexact trap takes precedence over Rounded, and any Rounded trap takes precedence
over Clamped.

WORK IN PROGRESS ! (1.21, 2017/07/26)

I follow the Python terminology: a trapped signal means it raises an exception which for us means an expandable error message with some possible user interaction. In this WIP state, the interaction is commented out. A non-trapped signal or condition would activate a (presumably silent) handler.

Here, no signal-raising condition is "ignored" and all are "trapped" which means that error handlers are never activated, thus left in garbage state in the code.

Various conditions can raise the same signal.

Only signals, not conditions, raise Flags.

If a signal is ignored it does not raise a Flag, but it activates the signal handler (by default now no signal is ignored.)

If a signal is not ignored it raises a Flag and then if it is not trapped it activates the handler of the `_condition_`.

If trapped (which is default now) an «exception» is raised, which means an expandable error message (I copied over the LaTeX3 code for expandable error messages, basically) interrupts the TeX run. In future, user input could be solicited, but currently this is commented out.

For now macros to reset flags are done but without public interface nor documentation.

Only four conditions are currently possibly encountered:

- `InvalidOperation`
- `DivisionByZero`
- `DivisionUndefined` (which signals `InvalidOperation`)
- `Underflow`

I did it quickly, anyhow this will become more palpable when some of the Decimal Specification is actually implemented. The plan is to first do the X3.274 norm, then more complete implementation will follow... perhaps...

Routines handling integers as lists of token digits

Routines handling big integers which are lists of digit tokens with no special additional structure.

Some routines do not accept non properly terminated inputs like "\the\numexpr1", or "\the\mathcode`- ", others do.

These routines or their sub-routines are mainly for internal usage.

4.5 \xint_cuz_small

`\XINT_cuz_small` removes leading zeroes from the first eight digits. Expands following `\romannumerals0`. At least one digit is produced.

```
127 \def\XINT_cuz_small#1{%
128 \def\XINT_cuz_small ##1##2##3##4##5##6##7##8%
129 {%
130   \expandafter#1\the\numexpr ##1##2##3##4##5##6##7##8\relax
131 }}\XINT_cuz_small{ }%
```

4.6 \xintNum, \xintiNum

For example \xintNum {-----00000000000003}

Very old routine got completely rewritten at 1.21.

New code uses `\numexpr` governed expansion and fixes some issues of former version particularly regarding inputs of the `\numexpr... \relax` type without `\the` or `\number` prefix, and/or possibly no terminating `\relax`.

`\xintiNum{\numexpr 1}\foo` in earlier versions caused premature expansion of `\foo`.

\xintiNum{\the\numexpr 1} was ok, but a bit luckily so.

Also, up to 1.2k inclusive, the macro fetched tokens eight by eight, and not nine by nine as is done now. I have no idea why.

\xintNum gets redefined by **xintfrac**.

```

147     \xint_gob_til_xint: #9\XINT_num_end\xint:
148     #1#2#3#4#5#6#7#8#9%
149     \ifnum \numexpr #1#2#3#4#5#6#7#8#9+\xint_c_ = \xint_c_

```

means that so far only signs encountered, (if syntax is legal) then possibly zeroes or a terminated or not terminated *\numexpr* evaluating to zero In that latter case a correct zero will be produced in the end.

```

150         \expandafter\XINT_num_loop
151     \else

```

non terminated *\numexpr* (with nine tokens total) are safe as after *\fi*, there is then *\xint*:

```

152         \expandafter\relax
153     \fi
154 }%
155 \def\XINT_num_end\xint:#1\xint:{#1+\xint_c_}\xint:{}% empty input ok
156 \def\XINT_num_cleanup #1\xint:#2\Z { #1}%

```

4.7 *\xintiiSgn*

1.21 made *\xintiiSgn* robust against non terminated input.

1.20 deprecates here *\xintSgn* (it requires *xintfrac.sty*).

```

157 \def\xintiiSgn {\romannumeral0\xintiiisgn }%

```

Blocks of eight digits

The lingua of release 1.2.

4.19 \XINT_cuz

This (launched by `\romannumeral0`) iterately removes all leading zeroes from a sequence of 8N digits ended by `\R`.

Rewritten for 1.21, now uses `\numexpr` governed expansion and `\ifnum` test rather than delimited gobbling macros.

Note 2015/11/28: with only four digits the *gob_til_fourzeroes* had proved in some old testing faster than *\ifnum* test. But with eight digits, the execution times are much closer, as I tested back then.

```

388 \def\xint_cuz_byviii_done #1\R { #1}%
389 \def\xint_cuz_byviii_e\R #1\xint_cuz_byviii_done #2\R{ #2}%

```

4.21 \XINT_unsep_loop

This is used as

```

\the\numexpr0\xint_unsep_loop (blocks of 1<8digits>!)
    \xint_!2!3!4!5!6!7!8!9!\xint_!0\xint_c_i\relax

```

It removes the 1's and !'s, and outputs the $8N$ digits with a 0 token as prefix which will have to be cleaned out by caller.

Actually it does not matter whether the blocks contain really 8 digits, all that matters is that they have 1 as first digit (and at most 9 digits after that to obey the TeX-*\numexpr* bound).

Done at 1.21 for usage by other macros. The similar code in earlier releases was strangely in $O(N^2)$ style, apparently to avoid some memory constraints. But these memory constraints related to *\numexpr* chaining seems to be in many places in *xint* code base. The 1.21 version is written in the 1.2i style of *\xintInc* etc... and is compatible with some 1! block without digits among the treated blocks, they will disappear.

```

390 \def\xint_unsep_loop #1!#2!#3!#4!#5!#6!#7!#8!#9!%
391 {%
392     \expandafter\xint_unsep_clean

4.24 \XINT_div_unsepR

This is used by division to remove separators from the produced remainder. The remainder is here in correct order. It must be cleaned of leading zeroes, possibly all the way.

Also rewritten for 1.21, the 1.2 version was $O(N^2)$ style.

Terminator \xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax\R

We have a need for something like \R because it is not guaranteed the thing is not actually zero.

```
431 \def\XINT_div_unsepR

530 }%

```

Core arithmetic

The four operations have been rewritten entirely for release 1.2. The new routines works with separated blocks of eight digits. They all measure first the lengths of the arguments, even addition and subtraction (this was not the case with xintcore.sty 1.1 or earlier.)

The technique of chaining `\the\numexpr` induces a limitation on the maximal size depending on the size of the input save stack and the maximum expansion depth. For the current (TL2015) settings (5000, resp. 10000), the induced limit for addition of numbers is at 19968 and for multiplication it is observed to be 19959 (valid as of 2015/10/07).

Side remark: I tested that `\the\numexpr` was more efficient than `\number`. But it reduced the allowable numbers for addition from 19976 digits to 19968 digits.

4.33 `\xintiiAdd`

1.21: `\xintiiAdd` made robust against non terminated input.

2 as first token of #1 stands for "no carry", 3 will mean a carry (we are adding 1<8digits> to 1<8digits>.) Version 1.2c has terminators of the shape 1;!, replacing the \Z! used in 1.2.

Call: `\the\numexpr\XINT_add_a #1#;!1;!1;!1;!W#2#;!1;!1;!1;!W` where #1 and #2 are blocks of `1<8d>`, and #1 is at most as long as #2. This last requirement is a bit annoying (if one wants to do recursive algorithms but not have to check lengths), and I will probably remove it at some point.

Output: blocks of $1 < 8d!$ representing the addition, (least significant first), and a final $1;!$. In recursive algorithm this $1;!$ terminator can thus conveniently be reused as part of input terminator (up to the length problem).

4.34 \xintiiCmp

Moved from *xint.sty* to *xintcore.sty* and rewritten for 1.21.

1.21's *\xintiiCmp* is robust against non terminated input.

1.20 deprecates *\xintCmp*, with *xintfrac* loaded it will get overwritten anyhow.

```

4.35 \xintiiSub

Entirely rewritten for 1.2.

Refactored at 1.21. I was initially aiming at clinching some internal format of the type $1<8\text{digits}>!\dots!1<8\text{digits}>!$ for chaining the arithmetic operations (as a preliminary step to deciding upon some internal format for *xintfrac* macros), thus I wanted to uniformize delimiters in particular and have some core macros inputting and outputting such formats. But the way division is implemented makes it currently very hard to obtain a satisfactory solution. For subtraction I got there almost, but there was added overhead and, as the core sub-routine still assumed the shorter number will be positioned first, one would need to record the length also in the basic internal format, or add the overhead to not make assumption on which one is shorter. I thus but back-tracked my steps but in passing I improved the efficiency (probably) in the worst case branch.

Sadly this 1.21 refactoring left an extra ! in macro \XINT_sub_l_Ida. This bug shows only in rare circumstances which escaped out test suite :(Fixed at 1.2q.

The other reason for backtracking was in relation with the decimal numbers. Having a core format in base 10^8 but ultimately the radix is actually 10 leads to complications. I could use radix 10^8 for \xintiiexpr only, but then I need to make it compatible with sub-\xintiiexpr in \xintexpr, etc... there are many issues of this type.

I considered also an approach like in the 1.21 \xintiiCmp, but decided to stick with the method here for now.

The post-processing (clean-up of zeros, or rescue of situation with A-B where actually B turns out bigger than A) will be done by a macro which depends on circumstances and will be initially last token before the reversion done by \XINT_unrevbyviii.

```
848 \def\XINT_sub_out {\XINT_unrevbyviii{}}%
```

1 as first token of #1 stands for "no carry", 0 will mean a carry.

Call: \the\numexpr

```
    \XINT_sub_a 1#11;!1;!1;!1;!1\W
        #21;!1;!1;!1;!1\W
```

where #1 and #2 are blocks of $1<8d>!$, #1 (=B) *must* be at most as long as #2 (=A), (in radix 10^8) and the routine wants to compute $\#2 - \#1 = A - B$

1.21 uses $1;!$ delimiters to match those of addition (and multiplication). But in the end I reverted the code branch which made it possible to chain such operations keeping internal format in 8 digits blocks throughout.

\numexpr governed expansion stops with various possibilities:

- Type Ia: #1 shorter than #2, no final carry
- Type Ib: #1 shorter than #2, a final carry but next block of #2 > 1
- Type Ica: #1 shorter than #2, a final carry, next block of #2 is final and = 1
- Type Icb: as Ica except that 00000001 block from #2 was not final
- Type Id: #1 shorter than #2, a final carry, next block of #2 = 0
- Type IIa: #1 same length as #2, turns out it was $\leq \#2$.
- Type IIb: #1 same length as #2, but turned out $> \#2$.

Various type of post actions are then needed:

- Ia: clean up of zeros in most significant block of 8 digits
- Ib: as Ia

- Ic: there may be significant blocks of 8 zeros to clean up from result. Only case Ica may have arbitrarily many of them, case Icb has only one such block.

- Id: blocks of 99999999 may propagate and there might be final zero block created which has to be cleaned up.

- IIa: arbitrarily many zeros might have to be removed.

- IIb: We wanted $\#2 - \#1 = -(\#1 - \#2)$, but we got $10^{8N} + \#2 - \#1 = 10^{8N} - (\#1 - \#2)$. We need to do the correction then we are as in IIa situation, except that final result can not be zero.

The 1.21 method for this correction is (presumably, testing takes lots of time, which I do not have) more efficient than in 1.2 release.

```

B terminated. Have we reached the end of A (necessarily at least as long as B) ? (we are computing A-B, digits of B come first).

If not, then we are certain that even if there is carry it will not propagate beyond the end of A. But it may propagate far transforming chains of 00000000 into 99999999, and if it does go to the final block which possibly is just $1<00000001>!$, we will have those eight zeros to clean up.

If A and B have the same length (in base 10^8) then arbitrarily many zeros might have to be cleaned up, and if $A < B$, the whole result will have to be complemented first.

This is the case where both operands have same 10^8 -base length.

We were handling $A-B$ but perhaps $B>A$. The situation with $A=B$ is also annoying because we then have to clean up all zeros but don't know where to stop (if $A>B$ the first non-zero 8 digits block would tell use when).

Here again we need to grab $\#3\W$ to position the actually used terminating delimiters.

Call:

```
\the\numexpr \XINT_mul_loop 100000000!1;!\\W #11;!\\W #21;!
```

where #1 and #2 are (globally reversed) blocks $1 < \text{sd}!.$. Its is generally more efficient if #1 is the shorter one, but a better recipe is implemented in `\XINT_mul_checklengths`. One may call `\XINT_mul_loop` directly (but multiplication by zero will produce many 100000000! blocks on output).

Ends after having produced: $1<8d>!\dots1<8d>1!;$. The last 8-digits block is significant one. It can not be 100000000! except if the loop was called with a zero operand.

Thus \XINT_mul_loop can be conveniently called directly in recursive routines, as the output terminator can serve as input terminator, we can arrange to not have to grab the whole thing again.

```

1.2 small and mini multiplication in base 10^8 with carry. Used by the main multiplication routines. But division, float factorial, etc.. have their own variants as they need output with specific constraints.

The minimulwc has $1<8\text{digits carry}>.<4 \text{ high digits}>.<4 \text{ low digits!}<8\text{digits}>$.

It produces a block $1<8d>!$ and then jump back into \XINT_smallmul_a with the new 8digits carry as argument. The \XINT_smallmul_a fetches a new $1<8d>!$ block to multiply, and calls back \XINT_minimul_wc having stored the multiplicand for re-use later. When the loop terminates, the final carry is checked for being nul, and in all cases the output is terminated by a 1;!

Multiplication by zero will produce blocks of zeros.

4.37 \xintiiDivision

Completely rewritten for 1.2.

WARNING: some comments below try to describe the flow of tokens but they date back to xint 1.09j and I updated them on the fly while doing the 1.2 version. As the routine now works in base 10^8,

not 10^4 and "drops" the quotient digits, rather than store them upfront as the earlier code, I may well have not correctly converted all such comments. At the last minute some previously #1 became stuff like #1#2#3#4, then of course the old comments describing what the macro parameters stand for are necessarily wrong.

Side remark: the way tokens are grouped was not essentially modified in 1.2, although the situation has changed. It was fine-tuned in xint 1.0/1.1 but the context has changed, and perhaps I should revisit this. As a corollary to the fact that quotient digits are now left behind thanks to the chains of \numexpr, some macros which in 1.0/1.1 fetched up to 9 parameters now need handle less such parameters. Thus, some rationale for the way the code was structured has disappeared.

1.21: \xintiiDivision et al. made robust against non terminated input.

#1 = A, #2 = B. On calcule le quotient et le reste dans la division euclidienne de A par B: A=BQ+R, $0 \leq R < |B|$.

Donc attention malgré son nom \XINT_div_prepare va jusqu'au bout. C'est donc en fait l'entrée principale (pour $B>0$, $A>0$) mais elle va regarder si B est $< 10^8$ et s'il vaut alors 1 ou 2, et si $A < 10^8$. Dans tous les cas le résultat est produit sous la forme $\{Q\}\{R\}$, avec Q et R sous leur forme final. On doit ensuite ajuster si le B ou le A initial était négatif. Je n'ai pas fait beaucoup d'efforts pour être un minimum efficace si A ou B n'est pas positif.

```

Special very small multiplication for division. We only need to cater for multiplicands from 1 to 9. The ending is different from standard verysmallmul, a zero carry is not suppressed. And no final 1;! is added. If multiplicand is just 1 let's not forget to add the zero carry 100000000! at the end.

```

Ici $B < 10^8$ (et est > 2). On exécute

$\expandafter\XINT_sdiv_out\the\numexpr\XINT_smalldivx_a \ x.1B!1<8d>!\dots1<8d>!1;$! avec $x = \text{round}(B/2)$, $1B=10^8+B$, et A déjà en blocs $1<8d>!$ (non renversés). Le $\the\numexpr\XINT_smalldivx_a$ va produire $Q\backslash Z R\backslash W$ avec un $R<10^8$, et un Q sous forme de blocs $1<8d>!$ terminé par $1!$ et nécessitant le nettoyage du premier bloc. Dans cette branche le B n'a pas été multiplié par une puissance de 10, il peut avoir moins de huit chiffres.

```

1640 \def\XINT_sdiv_out #1;!#2!%
1641   {\expandafter
1642    {\romannumerals0\XINT_unsep_cuzsmall

Cette routine fait la division euclidienne d'un nombre de seize chiffres par $#1 = C$ = diviseur sur huit chiffres $\geq 10^7$, avec $#2$ = sa moitié utilisée dans `\numexpr` pour contrebalancer l'arrondi (ARRRRRRGGGGHHHH) fait par $/$. Le nombre divisé $XY = X*10^8+Y$ se présente sous la forme $1<8chiffres>!1<8chiffres>!$ avec plus significatif en premier.

Seul le quotient est calculé, pas le reste. En effet la routine de division principale va utiliser ce quotient pour déterminer le "grand" reste, et le petit reste ici ne nous serait d'à peu près aucune utilité.

ATTENTION UNIQUEMENT UTILISÉ POUR DES SITUATIONS OÙ IL EST GARANTI QUE $X < C$! (et C au moins 10^7) le quotient euclidien de $X*10^8+Y$ par C sera donc $< 10^8$. Il sera renvoyé sous la forme $1<8chiffres>$.

Attention to not move DivRound code beyond that point. A bit of abuse here for divbyzero defaulted-to value, which happily works in both.

4.46 \xintiiPow

The exponent is not limited but with current default settings of tex memory, with xint 1.2, the maximal exponent for 2^N is $N = 2^{17} = 131072$.

1.2f Modifies the initial steps: 1) in order to be able to let more easily `\xintiPow` use `\xintNum` on the exponent once `xintfrac.sty` is loaded; 2) also because I noticed it was not very well coded. And it did only a `\numexpr` on the exponent, contradicting the documentation related to the "i" convention in names.

1.21: `\xintiIPow` made robust against non terminated input.

B = #1 > 0 , A = #2 > 1. Earlier code checked if size of B did not exceed a given limit (for example 131000).

The 1.2c `\XINT_mul_loop` can be called directly even with small arguments, hence the "butcheck-ifsmall" is not a necessity as it was earlier with 1.2. On 2^{30} , it does bring roughly a 40% time gain though, and 30% gain for 2^{60} . The overhead on big computations should be negligible.

4.47 \xintiiFac

Moved here from xint.sty with release 1.2 (to be usable by \bnumexpr).

An `\xintiFac` is needed by `xintexpr.sty`. Prior to 1.2o it was defined here as an alias to `\xintiiFac`, then redefined by `xintfrac` to use `\xintNum`. This was incoherent. Contrarily to other similarly named macros, `\xintiiFac` uses `\numexpr` on its input. This is also incoherent with the naming scheme, alas.

Note (end november 2015): I also tried out a quickly written recursive (binary split) implementation.

```

\or
    \expandafter\xint_secondofthree
\else
    \expandafter\xint_thirdofthree
\fi
{\the\numexpr\xint_c_x^viii+\#1!1;!}%
{\the\numexpr\xint_c_x^viii+\#1*\#2!1;!}%
{\expandafter\vfac\the\numexpr (#1+\#2)/\xint_c_ii.\#1.\#2.%}
}%
\def\vfac #1.#2.#3.%
{%
\expandafter
\wfac\expandafter
{\romannumeral-`0\expandafter
\ufac\expandafter{\the\numexpr #1+\xint_c_i}\{\#3\}}%

\def\zfac {\the\numexpr\XINT_mul_loop 100000000!1;\!\W }% core multiplication...
\catcode`_ 8
\catcode`^ 7

```

and I was quite surprised that it was only about 1.6x--2x slower in the range N=200 to 2000 than the `\xintiiFac` here which attempts to be smarter...

Note (2017, 1.21): I found out some code comment of mine that the code here should be more in the style of `\xintiiBinomial`, but I left matters untouched.

1.2o modifies `\xintiFac` to be coherent with `\xintiBinomial`: only with `xintfrac.sty` loaded does it use `\xintNum`. It is documented only as macro of `xintfrac.sty`, not as macro of `xint.sty`.

With release 1.1 the core arithmetic routines *\xintiiAdd*, *\xintiiSub*, *\xintiiMul*, *\xintiiQuo*, *\xintiiPow* were separated to be the main component of the then new *xintcore*.

At 1.3 the macros deprecated at 1.20 got all removed.

1.3b adds randomness related macros.

5.4 \xintLen, \xintiLen

\xintLen gets extended to fractions by *xintfrac.sty*: A/B is given length $\text{len}(A)+\text{len}(B)-1$ (somewhat arbitrary). It applies \xintNum to its argument. A minus sign is accepted and ignored.

For parallelism with \xintiNum/\xintNum, 1.2o defines \xintiLen.

\xintLen gets redefined by *xintfrac*.

```

```

5.6 \xintReverseDigits

1.2.

This puts digits in reverse order, not suppressing leading zeros after reverse. Despite lacking the "ii" in its name, it does not apply \xintNum to its argument (contrarily to \xintLen, this is not very coherent).

1.2l variant is robust against non terminated \the\numexpr input.

This macro is currently not used elsewhere in xint code.

5.7 \xintiiE

Originally was used in `\xintiiexpr`. Transferred from `xintfrac` for 1.1. Code rewritten for 1.2i. `\xintiiE{x}{e}` extends `x` with `e` zeroes if `e` is positive and simply outputs `x` if `e` is zero or negative. Attention, le comportement pour $e < 0$ ne doit pas être modifié car `\xintMod` et autres macros en dépendent.

```

134 \def\XINT_iie_neg #1.#2;{ #2}%

```

5.8 \xintDecSplit

DECIMAL SPLIT

The macro `\xintDecSplit {x}{A}` cuts A which is composed of digits (leading zeroes ok, but no sign) (*) into two (each possibly empty) pieces L and R. The concatenation LR always reproduces A.

The position of the cut is specified by the first argument x. If x is zero or positive the cut location is x slots to the left of the right end of the number. If x becomes equal to or larger than the length of the number then L becomes empty. If x is negative the location of the cut is |x| slots to the right of the left end of the number.

(*) versions earlier than 1.2i first replaced A with its absolute value. This is not the case anymore. This macro should NOT be used for A with a leading sign (+ or -).

Entirely rewritten for 1.2i (2016/12/11).

Attention: `\xintDecSplit` not robust against non terminated second argument.

5.13 \xintDSx

--> Attention le cas $x=0$ est traité dans la même catégorie que $x > 0$ --
 si $x < 0$, fait $A \rightarrow A \cdot 10^{|x|}$
 si $x \geq 0$, et $A \geq 0$, fait $A \rightarrow \{ \text{quo}(A, 10^x) \} \{ \text{rem}(A, 10^x) \}$
 si $x \geq 0$, et $A < 0$, d'abord on calcule $\{ \text{quo}(-A, 10^x) \} \{ \text{rem}(-A, 10^x) \}$
 puis, si le premier n'est pas nul on lui donne le signe -
 si le premier est nul on donne le signe - au second.

On peut donc toujours reconstituer l'original A par $10^x Q \pm R$ où il faut prendre le signe plus si Q est positif ou nul et le signe moins si Q est strictement négatif.

Rewritten for 1.2i, this was old code.

```

5.38 \xintifTrueAelseB, \xintifFalseAelseB

1.09i. 1.2i has removed deprecated \xintifTrueFalse, \xintifTrue.

1.2o uses \xintiiifNotZero, see comments to \xintAND etc... This will work fine with arguments being nested *xintfrac.sty* macros, without the overhead of \xintNum or \xintRaw parsing.

```
511 \def\xintifTrueAelseB {\romannumeral0\xintiiifnotzero}%
512 \def\xintifFalseAelseB{\romannumeral0\xintiiifzero}%
```

5.39 \xintIsTrue, \xintIsFalse

1.09c. Suppressed at 1.2o. They seem not to have been documented, fortunately.

```
513 \%let\xintIsTrue \xintIsNotZero
514 \%let\xintIsFalse\xintIsZero
```

5.40 \xintNOT

1.09c. But it should have been called \xintNOT, not \xintNot. Former denomination deprecated at 1.2o. Besides, the macro is now defined as ii-type.

```
515 \def\xintNOT{\romannumeral0\xintiiiszero}%
```

5.41 \xintAND, \xintOR, \xintXOR

Added with 1.09a. But they used \xintSgn, etc... rather than \xintiiSgn. This brings \xintNum overhead which is not really desired, and which is not needed for use by xintexpr.sty. At 1.2o I modify them to use only ii macros. This is enough for sign or zeroness even for xintfrac format, as manipulated inside the \xintexpr. Big hesitation whether there should be however \xintiiAND outputting 1 or 0 versus an \xintAND outputting 1[0] versus 0[0] for example.

```

```

5.42 \xintANDof

New with 1.09a. \xintANDof works also with an empty list. Empty items however are not accepted.

1.2l made \xintANDof robust against non terminated items.

1.2o's \xintifTrueAelseB is now an ii macro, actually.

1.4. This macro as well as ORof and XORof were formally not used by xintexpr, which uses comma separated items, but at 1.4 xintexpr uses braced items. And the macros here got slightly refactored and \XINT_ANDof added for usage by xintexpr and the NewExpr hook. For some random reason I decided to use ^ as delimiter this has to do that other macros in xintfrac in same family (such as \xintGCDof, \xintSum) also use \xint: internally and although not strictly needed having two separate ones clarifies.

```
527 \def\xintANDof {\romannumeral0\xintandof }%

5.46 *\xintiiMin*

\xintnum added New with 1.09a. I add *\xintiiMin* in 1.1 and mark as deprecated *\xintMin*, re-named *\xintiMin*. *\xintMin* NOW REMOVED (1.2, as *\xintMax*, *\xintMaxof*), only provided by *\xintfracnameimp*.

At 1.2m, a long-standing bug was fixed: *\xintiiMin* had the overhead of applying *\xintNum* to its arguments due to use of a sub-macro of *\xintGeq* code to which this overhead was added at some point.

And on this occasion I reduced even more number of times input is grabbed.

5.51 \xintiiSquareRoot

First done with 1.08.

- 1.1 added \xintiiSquareRoot.
- 1.1a added \xintiiSqrtR.

1.2f (2016/03/01-02-03) has rewritten the implementation, the underlying mathematics remaining about the same. The routine is much faster for inputs having up to 16 digits (because it does it all with \numexpr directly now), and also much faster for very long inputs (because it now fetches only the needed new digits after the first 16 (or 17) ones, via the geometric sequence 16, then 32, then 64, etc...; earlier version did the computations with all remaining digits after a suitable starting point with correct 4 or 5 leading digits). Note however that the fetching of tokens is via intrinsically $O(N^2)$ macros, hence inevitably inputs with thousands of digits start being treated less well.

Actually there is some room for improvements, one could prepare better input X for the upcoming treatment of fetching its digits by 16, then 32, then 64, etc...

Incidentally, as \xintiiSqrt uses subtraction and subtraction was broken from 1.2 to 1.2c, then for another reason from 1.2c to 1.2f, it could get wrong in certain (relatively rare) cases. There was also a bug that made it unneedlessly slow for odd number of digits on input.

1.2f also modifies \xintFloatSqrt in xintfrac.sty which now has more code in common with here and benefits from the same speed improvements.

1.2k belatedly corrects the output to {1}{1} and not 11 when input is zero. As braces are used in all other cases they should have been used here too.

Also, 1.2k adds an \xintiSqrtR macro, for coherence as \xintiSqrt is defined (and mentioned in user manual.)

5.53 \xintiiBinomial

2015/11/28-29 for 1.2f.

2016/11/19 for 1.2h: I truly can't understand why I hard-coded last year an error-message for arguments outside of the range for binomial formula. Naturally there should be no error but a rather a 0 return value for `binomial(x,y)`, if $y < 0$ or $x < y$!

I really lack some kind of infinity or NaN value.

1.2o deprecates `\xintiBinomial`. (which `xintfrac.sty` redefined to use `\xintNum`)

$y=x-k+1$. $j=1..k$. On va évaluer par $y/1*(y+1)/2*(y+2)/3$ etc... On essaie de regrouper de manière à utiliser au mieux \numexpr . On peut aller jusqu'à $x=10000$ car $9999*10000 < 10^8$. $463*464*465 = 99896880$, $98*99*100*101 = 97990200$. On va vérifier à chaque étape si on dépasse un seuil. Le style de l'implémentation diffère de celui que j'avais utilisé pour \xintiiFac . On pourrait tout-à-fait avoir une `verybigloop`, mais bon. Je rajoute aussi un `verysmall`. Le traitement est un peu différent pour elle afin d'aller jusqu'à $x=29$ (et pas seulement 26 si je suivais le modèle des autres, mais je veux pouvoir faire $\binom{29}{1}$, $\binom{29}{2}$, ... en `vsmall`).

*y.j.k. La partie very small. y est au plus 26 (non 29 mais retesté dans \XINT_binom_vsmalloop_a), et tous les binomial(29,n) sont <10^8. On peut donc faire y(y+1)(y+2)(y+3) et aussi il y a le fait que etex fait a*b/c en double precision. Pour ne pas bifurquer à la fin sur smallloop, si n=27, 27, ou 29 on procède un peu différemment des autres boucles. Si je testais aussi #1 après #3-#2 pour les autres il faudrait des terminaisons différentes.*

5.54 \xintiiPFactorial

2015/11/29 for 1.2f. Partial factorial pfac(a,b)=(a+1)...b, only for non-negative integers with a<=b<10^8.

1.2h (2016/11/20) removes the non-negativity condition. It was a bit unfortunate that the code raised `\xintError:OutOfRangePFac` if $0 \leq a \leq b < 10^8$ was violated. The rule now applied is to interpret `pfac(a,b)` as the product for $a < j \leq b$ (not as a ratio of Gamma function), hence if $a \geq b$, return 1 because of an empty product. If $a < b$: if $a < 0$, return 0 for $b \geq 0$ and $(-1)^{b-a}$ times $|b| \dots (|a|-1)$ for $b < 0$. But only for the range $0 \leq a \leq b < 10^8$ is the macro result to be considered as stable.

This raises following annex question: immediately after setting the seed is it possible for `\xintUniformDeviate{N}` where $N > 0$ has exactly eight digits to return either 0 or $N - 1$? It could be that this is never the case, then there is a bias in `randrange()`. Of course there are anyhow only 2^{28} seeds so `randrange(10^X)` is by necessity biased when executed immediately after setting the seed, if X is at least 9.

Here too, overhead is not such a problem. The idea is that we got by extraordinary same first 8 digits as upper range bound so we pick at random the remaining needed digits in one go and compare with the upper bound. If too big, we start again with another random 8 leading digits in given range. No need to aim at any kind of efficiency for the check and loop back.

6 Package *xintbinhex* implementation

.1	Catcodes, ε - \TeX and reload detection	162	.6	\backslash xintDecToBin	167
.2	Package identification	163	.7	\backslash xintHexToDec	168
.3	Constants, etc...	163	.8	\backslash xintBinToDec	170
.4	Helper macros	164	.9	\backslash xintBinToHex	171
.4.1	\backslash XINT_zeroes_foriv	164	.10	\backslash xintHexToBin	172
.5	\backslash xintDecToHex	164	.11	\backslash xintCHexToBin	172

The commenting is currently (2020/02/19) very sparse.

The macros from 1.08 (2013/06/07) remained unchanged until their complete rewrite at 1.2m (2012/07/31).

At 1.2n dependencies on *xintcore* were removed, so now the package loads only *xintkernel* (this could have been done earlier).

Also at 1.2n, macros evolved again, the main improvements being in the increased allowable sizes of the input for \backslash xintDecToHex, \backslash xintDecToBin, \backslash xintBinToHex. Use of \backslash csname governed expansion at some places rather than \backslash numexpr with some clean-up after it.

6.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

The 1.2n inserted exclamations marks, which when bumping back from `\XINT_dthb_again` gave rise to a `\numexpr`-loop which gathered the ! delimited arguments and inserted `\expandafter\XINT_dthb_update\the\numexpr` dynamically. The 1.2o trick is to insert it here immediately. Then at `\XINT_dthb_again` the `\numexpr` will trigger an already prepared chain.

The crux of the thing is handling of #3 at `\XINT_dthb_update_a`.

```

137 \def\XINT_dthb_exclam {!\XINT_dthb_exclam\relax

```

We only clean-up up to 3 zero hexadecimal digits, as output was produced in chunks of 4 hex digits. If input had no leading zero, output will have none either. If input had many leading zeroes, output will have some number (unspecified, but a recipe can be given...) of leading zeroes...

The coding is for varying a bit, I did not check if efficient, it does not matter.

6.6 *\xintDecToBin*

Complete rewrite at 1.2m in the 1.2 style. Also, 1.2m is robust against non terminated inputs.

Revisited at 1.2n like in *\xintDecToHex*: increased maximal size.

An input without leading zeroes gives an output without leading zeroes.

Most of the code canvas is shared with *\xintDecToHex*.

```

6.7 `\xintHexToDec`

Completely (and belatedly) rewritten at 1.2m in the 1.2 style.

1.2m version robust against non terminated inputs, but there is no primitive from TeX which may generate hexadecimal digits and provoke expansion ahead, afaik, except of course if decimal digits are treated as hexadecimal. This robustness is not on purpose but from need to expand argument and then grab it again. So we do it safely.

Increased maximal size at 1.2n.

1.2m version robust against non terminated inputs.

An input without leading zeroes gives an output without leading zeroes.

```

7 Package *xintgcd* implementation

.1	Catcodes, ε - \TeX and reload detection	174	.5	\backslash xintBezoutAlgorithm	180
.2	Package identification	175	.6	\backslash xintTypesetEuclideAlgorithm	182
.3	\backslash xintBezout	175	.7	\backslash xintTypesetBezoutAlgorithm	183
.4	\backslash xintEuclideAlgorithm	179			

The commenting is currently (2020/02/19) very sparse.

Release 1.09h has modified a bit the \backslash xintTypesetEuclideAlgorithm and \backslash xintTypesetBezoutAlgorithm layout with respect to line indentation in particular. And they use the *xinttools* \backslash xintloop rather than the Plain \TeX or \LaTeX 's \backslash loop.

Breaking change at 1.2p: \backslash xintBezout{A}{B} formerly had output {A}{B}{U}{V}{D} with AU-BV=D, now it is {U}{V}{D} with AU+BV=D.

From 1.1 to 1.3f the package loaded only *xintcore*. At 1.4 it now automatically loads both of *xint* and *xinttools* (the latter being in fact a requirement of \backslash xintTypesetEuclideAlgorithm and \backslash xintTypesetBezoutAlgorithm since 1.09h).

At 1.4 \backslash xintGCD, \backslash xintLCM, \backslash xintGCDof, and \backslash xintLCMof are removed from the package: they are provided only by *xintfrac* and they handle general fractions, not only integers.

Changed
at 1.4!

The original integer-only macros have been renamed into respectively \backslash xintiiGCD, \backslash xintiiLCM, \backslash xintiiGCDof, and \backslash xintiiLCMof and got relocated into *xint* package.

7.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

7.3 \xintBezout

\xintBezout{#1}{#2} produces {U}{V}{D} with $UA+VB=D$, $D = \text{PGCD}(A, B)$ (non-positive), where #1 and #2 f-expand to big integers A and B.

I had not checked this macro for about three years when I realized in January 2017 that \xintBezout{A}{B} was buggy for the cases $A = 0$ or $B = 0$. I fixed that blemish in 1.2l but overlooked the other blemish that \xintBezout{A}{B} with A multiple of B produced a coefficient U as -0 in place of 0.

Hence I rewrote again for 1.2p. On this occasion I modified the output of the macro to be {U}{V}{D} with $AU+BV=D$, formerly it was {A}{B}{U}{V}{D} with $AU - BV = D$. This is quite breaking change!

Note in particular change of sign of V.

I don't know why I had designed this macro to contain {A}{B} in its output. Perhaps I initially intended to output {A//D}{B//D} (but forgot), as this is actually possible from outcome of the last iteration, with no need of actually dividing. Current code however arranges to skip this last update, as U and V are already furnished by the iteration prior to realizing that the last non-zero remainder was found.

Also 1.2l raised InvalidOperation if both A and B vanished, but I removed this behaviour at 1.2p.

    e = -e
puis calcul quotient reste et itération

We arrange for \xintiiMul sub-routine to be called only with positive arguments, thus skipping some un-needed sign parsing there. For that though we have to screen out the special cases A divides B, or B divides A. And we first want to exchange A and B if A < B. These special cases are the only one possibly leading to U or V zero (for A and B positive which is the case here.) Thus the general case always leads to non-zero U and V's and assigning a final sign is done simply adding a - to one of them, with no fear of producing -0.

We use the fact that the `\romannumeral-`0` (or equivalent) done by `\xintiiadd` will absorb the initial space token left by `\XINT_mul_plusplus` in its output.

We arranged for operands here to be always positive which is needed for `\XINT_mul_plusplus` entry point (last time I checked...). Admittedly this kind of optimization is not good for maintenance of code, but I can't resist temptation of limiting the shuffling around of tokens...

7.7 `\xintTypesetBezoutAlgorithm`

Pour Bezout on a: {N}{A}{0}{1}{D=r(n)}{B}{1}{0}{q1}{r1}{alpha1=q1}{beta1=1}{q2}{r2}{alpha2}{beta2}....{qN}{rN=0}{alphaN=A/D}{betaN=B/D}

Donc $4N+8$ termes: $U_1 = N$, $U_2 = A$, $U_5 = D$, $U_6 = B$, $q_1 = U_9$, $q_n = U_{4n+5}$, n au moins 1
 $r_n = U_{4n+6}$, n au moins -1

$\alpha(n) = U_{4n+7}$, n au moins -1

$\beta(n) = U_{4n+8}$, n au moins -1

1.09h uses `\xintloop`, and `\par` rather than `\endgraf`; and no more `\parindent0pt`

```

8.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.
The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%

66     \relax
67 }}\XINT_flen{ }%
```

8.5 \XINT_outfrac

Months later (2014/10/22): perhaps I should document what this macro does before I forget? from `{e}{N}{D}` it outputs `N/D[e]`, checking in passing if `D=0` or if `N=0`. It also makes sure `D` is not `< 0`. I am not sure but I don't think there is any place in the code which could call `\XINT_outfrac` with a `D < 0`, but I should check.

```

```

8.6 \XINT_inFrac

Parses fraction, scientific notation, etc... and produces $\{n\}\{A\}\{B\}$ corresponding to A/B times 10^n . No reduction to smallest terms.

Extended in 1.07 to accept scientific notation on input. With lowercase e only. The *xintexpr* parser does accept uppercase E also. Ah, by the way, perhaps I should at least say what this macro does? (belated addition 2014/10/22...), before I forget! It prepares the fraction in the internal format $\{\text{exponent}\}\{\text{Numerator}\}\{\text{Denominator}\}$ where Denominator is at least 1.

2015/10/09: this venerable macro from the very early days (1.03, 2013/04/14) has gotten a lifting for release 1.2. There were two kinds of issues:

1) use of \W, \Z, \T delimiters was very poor choice as this could clash with user input,
 2) the new \XINT_frac_gen handles macros (possibly empty) in the input as general as \A.\Be\C/\D.\Ee\F.
 The earlier version would not have expanded the \B or \E: digits after decimal mark were constrained to arise from expansion of the first token. Thus the 1.03 original code would have expanded only \A, \D, \C, and \F for this input.

This reminded me think I should revisit the remaining earlier portions of code, as I was still learning TeX coding when I wrote them.

Also I thought about parsing even faster the A/B[N] input, not expanding B, but this turned out to clash with some established uses in the documentation such as 1/\xintiiSqr{...}[0]. For the implementation, careful here about potential brace removals with parameter patterns such as like #1/#2#3[#4] for example.

While I was at it 1.2 added \numexpr parsing of the N, which earlier was restricted to be only explicit digits. I allowed [] with empty N, but the way I did it in 1.2 with \the\numexpr 0#1 was buggy, as it did not allow #1 to be a \count for example or itself a \numexpr (although such inputs

were not previously allowed, I later turned out to use them in the code itself, e.g. the float factorial of version 1.2f). The better way would be `\the\numexpr#1+\xint_c_` but 1.2f finally does only `\the\numexpr #1` and #1 is not allowed to be empty.

The 1.2 `\XINT_frac_gen` had two locations with such a problematic `\numexpr 0#1` which I replaced for 1.2f with `\numexpr#1+\xint_c_`.

Regarding calling the macro with an argument `A[<expression>]`, a / in the expression must be suitably hidden for example in `\firstofone` type constructs.

Note: when the numerator is found to be zero `\XINT_inFrac` *always* returns {0}{0}{1}. This behaviour must not change because 1.2g `\xintFloat` and `XINTinFloat` (for example) rely upon it: if the denominator on output is not 1, then `\xintFloat` assumes that the numerator is not zero.

As described in the manual, if the input contains a (final) [N] part, it is assumed that it is in the shape A[N] or A/B[N] with A (and B) not containing neither decimal mark nor scientific part, moreover B must be positive and A have at most one minus sign (and no plus sign). Else there will be errors, for example `-0/2[0]` would not be recognized as being zero at this stage and this could cause issues afterwards. When there is no ending [N] part, both numerator and denominator will be parsed for the more general format allowing decimal digits and scientific part and possibly multiple leading signs.

1.21 fixes frailty of `\XINT_infrac` (hence basically of all `xintfrac` macros) respective to non terminated `\numexpr` input: `\xintRaw{\the\numexpr1}` for example. The issue was that `\numexpr` sees the / and expands what's next. But even `\numexpr 1//` for example creates an error, and to my mind this is a defect of `\numexpr`. It should be able to trace back and see that / was used as delimiter not as operator. Anyway, I thus fixed this problem belatedly here regarding `\XINT_infrac`.

8.7 \XINT_frac_gen

Extended in 1.07 to recognize and accept scientific notation both at the numerator and (possible) denominator. Only a lowercase e will do here, but uppercase E is possible within an \xintexpr..\relax

Completely rewritten for 1.2 2015/10/10. The parsing handles inputs such as \A.\B\c\D.\Ee\f where each of \A, \B, \D, and \E may need f-expansion and \C and \F will end up in \numexpr.

1.2f corrects an issue to allow \C and \F to be \count variable (or expressions with \numexpr): 1.2 did a bad \numexpr0#1 which allowed only explicit digits for expanded #1.

```

8.8 \XINT_factortens

This is the core macro for `\xintREZ`. To be used as `\romannumeral0\XINT_factortens{...}`. Output is A.N. (formerly {A}{N}) where A is the integer stripped from trailing zeroes and N is the number of removed zeroes. Only for positive strict integers!

Completely rewritten at 1.3a to replace a double `\xintReverseOrder` by a direct `\numexpr` governed expansion to the end and back, à la 1.2. I should comment more... and perhaps improve again in future.

Testing shows significant gain at 100 digits or more.

```

8.13 \xintSPRaw, \xintFracToSci

This private macro was for usage by \xinttheexpr. It got moved here at 1.4.

Attention that \xintSPRaw assumes that if the number has no [N] part it does not have a fraction part /B either. Indeed this was the case always with 1.3f (parsing of an integer by \xintexpr does not add the [0] because the code is shared with \xintiiexpr and when there is /B, \xintexpr always

adds [0]; even *qfrac()* parses via *\xintRaw*; and *reduce()* internally uses *\xintIrr* whose outputs is A/B but it add [0]).

\xintFracToSci is now used in its place. As *reduce()* does not anymore append the [0] at 1.4, *\xintFracToSci* has to recognize A, A[N], A/B and A/B[N] but does not have to parse multiple plus or minus signs or scientific part etc like *\xintRaw* knows. It has to identify say 0/5 (although I don't think that can arise) and -0 is never occurring.

The difference with former case is that it outputs AeN/B hence does not anymore use the *xintfrac.sty* raw format. It will not print the /B if B=1 and not print the «eN» if N is zero.

If input is empty *\xintFracToSci* output is also empty, whereas *\xintRaw* produces 0/1[0] out of empty. But *\XINTexprprint* anyhow has its own special routine for empty input.

8.30 \xintTfrac

1.09i, for `frac` in `\xintexpr`. And `\xintFrac` is already assigned. T for truncation. However, potentially not very efficient with numbers in scientific notations, with big exponents. Will have to think it again some day. I hesitated how to call the macro. Same convention as in maple, but some people reserve fractional part to $x - \text{floor}(x)$. Also, not clear if I had to make it negative (or zero) if $x < 0$, or rather always positive. There should be in fact such a thing for each rounding function, `trunc`, `round`, `floor`, `ceil`.

```

8.31 \xintTrunc, \xintiTrunc

This of course has a long history. Only showing here some comments.

1.2i release notes: ever since its inception this macro was stupid for a decimal input: it did not handle it separately from the general fraction case $A/B[N]$ with $B>1$, hence ended up doing divisions by powers of ten. But this meant that nesting `\xintTrunc` with itself was very inefficient.

1.2i version is better. However it still handles $B > 1$, $N < 0$ via adding zeros to B and dividing with this extended B . A possibly more efficient approach is implemented in *\xintXTrunc*, but its logic is more complicated, the code is quite longer and making it f-expandable would not shorten it... I decided for the time being to not complicate things here.

1.4a (2020/02/18) adds handling of a negative first argument.

Zero input still gives single digit 0 output as I did not want to complicate the code. But if quantization gives 0, the exponent [D] will be there. Well actually eD because of problem that sign of original is preserved in output so we can have -0 and I can not use -0[D] notation as it is not legal for strict format. So I will use -0eD hence eD generally even though this means so slight suboptimality for *trunc()* function in *\xintexpr*.

The idea to give a meaning to negative D (in the context of optional argument to *\xintexpr*) was suggested a long time ago by Kpym (October 20, 2015). His suggestion was then to treat it as positive D but trim trailing zeroes. But since then, there is *\xintDecToString* which can be combined with *\xintREZ*, and I feel matters of formatting output require a whole module (or rather use existing third-party tools), and I decided to opt rather for an operation similar as the *quantize()* of Python Decimal module. I.e. we truncate (or round) to an integer multiple of a given power of 10.

Other reason to decide to do this is that it looks as if I don't even need to understand the original code to hack into its ending via *\XINT_trunc_G* or *\XINT_itrunc_G*. For the latter it looks as if logically I simply have to do nothing. For the former I simply have to add some eD postfix.

8.32 \xintTTrunc

1.1. Modified in 1.2i, it does simply *\xintiTrunc0* with no shortcut (the latter having been modified)

```

981 \def\xintTTrunc {\romannumeral0\xintttrunc }%
982 \def\xintttrunc {\xintitrunc\xint_c_}%

```

8.33 \xintNum

```
983 \let\xintnum \xintttrunc
```

8.34 \xintRound, \xintiRound

Modified in 1.2i.

It benefits first of all from the faster *\xintTrunc*, particularly when the input is already a decimal number (denominator B=1).

And the rounding is now done in 1.2 style (with much delay, sorry), like of the rewritten *\xintInc* and *\xintDec*.

At 1.4a, first argument can be negative. This is handled at *\XINT_trunc_G*.

8.35 *\xintXTrunc*

1.09j [2014/01/06] This is completely expandable but not f-expandable. Rewritten for 1.2i (2016/12/04):

- no more use of *\xintiloop* from *xinttools.sty* (replaced by *\xintreplicate...* from *xintkernel.sty*),

- no more use in 0>N>-D case of a dummy control sequence name via *\csname... \endcsname*

- handles better the case of an input already a decimal number

Need to transfer code comments into public dtx.

```

8.51 `\xintDivMod`

1.2p. `\xintDivMod{q1}{q2}` outputs $\{ \text{floor}(q1/q2) \} \{ q1 - q2 * \text{floor}(q1/q2) \}$. Attention that it relies on `\xintiE{x}{e}` returning *x* if *e* < 0 .

Modified (like `\xintAdd` and `\xintSub`) at 1.3 to use a l.c.m for final denominator of the "mod" part.

8.67 Floating point macros

For a long time the float routines dating back to releases 1.07/1.08a (May-June 2013) were not modified.

Since 1.2f (March 2016) the four operations first round their arguments to *\xinttheDigits*-floats (or P-floats), not (*\xinttheDigits*+2)-floats or (P+2)-floats as was the case with earlier releases.

The four operations addition, subtraction, multiplication, division have always produced the correct rounding of the theoretical exact value to P or *\xinttheDigits* digits when the inputs are decimal numbers with at most P digits, and arbitrary decimal exponent part.

From 1.08a to 1.2j, *\xintFloat* (and *\XINTinFloat* which is used to parse inputs to other float macros) handled a fractional input A/B via an initial replacement to A'/B' where A' and B' were A and B truncated to Q+2 digits (where asked-for precision is Q), and then they correctly rounded A'/B' to Q digits. But this meant that this rounding of the input could differ (by up to one unit in the last place) from the correct rounding of the original A/B to the asked-for number of digits (which until 1.2f in uses as auxiliary to the macros for the basic operations was 2 more than the prevailing precision).

Since 1.2k all inputs are correctly rounded to the asked-for number of digits (this was, I think, the case in the 1.07 release -- there are no code comments -- but was, afaicr, not very efficiently done, and this is why the 1.08a release opted for truncation of the numerator and denominator.)

Notice that in float expressions, the `/` is treated as operator, hence the above discussion makes a difference only for the special input form `qfloat(A/B)` or for an `\xintexpr A/B\relax` embedded in the float expression, with `A` or `B` having more digits than the prevailing float precision.

Internally there is no inner representation of P-floats as such !!!!!

The input parser will again compute the length of the mantissa on each use !!! This is obviously something that must be improved upon before implementation of higher functions.

Currently, special tricks are used to quickly recognize inputs having no denominators, or fractions whose numerators and denominators are not too long compared to the target precision P, and in particular P-floats or quotients of two such.

Another long-standing issue is that float multiplication will first compute the 2P or 2P-1 digits of the exact product, and then round it to P digits. This is sub-optimal for large P particularly as the multiplication algorithm is basically the schoolbook one, hence worse than quadratic in the TeX implementation which has extra cost of fetching long sequences of tokens.

8.68 \xintDigits, \xintSetDigits

1.3f modifies the (strange) original signature #1#2 for `\xintDigits` macro into #1=, allowing usage without colon. It also adds `\xintSetDigits`. Starred variants are added by `xintexpr.sty`.

```
1984 \mathchardef\XINTdigits 16
1985 \def\xintDigits #1=%
1986   {\afterassignment \xint_gobble_i \mathchardef\XINTdigits=%}
1987 \def\xinttheDigits {\number\XINTdigits }%
1988 \def\xintSetDigits #1{\mathchardef\XINTdigits=\numexpr#1\relax}%
```

8.69 \xintFloat

1.2f and 1.2g brought some refactoring which resulted in faster treatment of decimal inputs. 1.2i dropped use of some old routines dating back to pre 1.2 era in favor of more modern `\xintDSRr` for rounding. Then 1.2k improves again the handling of denominators B with few digits.

But the main change with 1.2k is a complete rewrite of the B>1 case in order to achieve again correct rounding in all cases.

The original version from 1.07 (May 2013) computed the exact rounding to P digits for all inputs. But from 1.08 on (June 2013), the macro handled A/B input by first truncating both A and B to at most P+2 digits. This meant that decimal input (arbitrarily long, with scientific part) was correctly rounded, but in case of fractional input there could be up to 0.6 unit in the last place difference of the produced rounding to the input, hence the output could differ from the correct rounding.

Example with 16 digits (the default): `\xintFloat {1/17597472569900621233}`

with `xintfrac 1.07:` 5.682634230727187e-20

with `xintfrac 1.08b--1.2j:` 5.682634230727188e-20

with `xintfrac 1.2k:` 5.682634230727187e-20

The exact value is 5.682634230727187499924124...e-20, showing that 1.07 and 1.2k produce the correct rounding.

Currently the code ends in a more costly branch in about 1 case among 500, where it does some extra operations (a multiplication in particular). There is a free parameter delta (here set at 4), I have yet to make some numerical explorations, to see if it could be favorable to set it to a higher value (with delta=5, there is only 1 exceptional case in 5000, etc...).

I have always hesitated about the policy of printing 10.00...0 in case of rounding upwards to the next power of ten. Already since 1.2f \XINTinFloat always produced a mantissa with exactly P digits (except for the zero value). Starting with 1.2k, \xintFloat drops this habit of printing 10.00..0 in such cases. Side note: the rounding-up detection worked when the input A/B was with numerator A and denominator B having each less than P+2 digits, or with B=1, else, it could happen that the output was a power of ten but not detected to be a rounding up of the original fraction. The value was ok, but printed 1.0...0eN with P-1 zeroes, not 10.0...0e(N-1).

I decided it was not worth the effort to enhance the algorithm to detect with 100% fiability all cases of rounding up to next power of ten, hence 1.2k dropped this.

To avoid duplication of code, and any extra burden on \XINTinFloat, which is the macro used internally by the float macros for parsing their inputs, we simply make now \xintFloat a wrapper of \XINTinFloat.

8.70 \XINTinFloat, \XINTinFloatS, \XINTiLogTen

This routine is like `\xintFloat` but produces an output of the shape `A[N]` which is then parsed faster as input to other float macros. Float operations in `\xintfloatexpr... \relax` use internally this format.

It must be used in form `\XINTinFloat[P]{f}`: the optional `[P]` is mandatory.

Since 1.2f, the mantissa always has exactly `P` digits even in case of rounding up to next power of ten. This simplifies other routines.

1.2g added a variant `\XINTinFloatS` which, in case of decimal input with less than the asked for precision `P` will not add extra zeros to the mantissa. For example it may output `2[0]` even if `P=500`, rather than the canonical representation `200...000[-499]`. This is how `\xintFloatMul` and `\xintFloatDiv` parse their inputs, which speeds-up follow-up processing. But `\xintFloatAdd` and `\xintFloatSub` still use `\XINTinFloat` for parsing their inputs; anyway this will have to be changed again when inner structure will carry upfront at least the length of mantissa as data.

Each time `\XINTinFloat` is called it at least computes a length. Naturally if we had some format for floats that would be dispensed of...

something like `<letterP><length of mantissa>.mantissa.exponent, etc...` not yet.

Since 1.2k, `\XINTinFloat` always correctly rounds its argument, even if it is a fraction with very big numerator and denominator. See the discussion of `\xintFloat`.

1.3e adds `\XINTiLogTen`.

```

Ici P=L. Le cas usuel dans *\xintfloatexpr*.

```
2093 \def\XINT_infloat_sp_quick 0.#1.#2.#3.{ #1[#3]}%
```

Ici #1=P-L est >0. L'exposant sera N-(P-L). #2=A. #3=P. #4=N.

18 mars 2016. En fait dans certains contextes il est sous-optimal d'ajouter les zéros. Par exemple quand c'est appelé par la multiplication ou la division, c'est idiot de convertir 2 en 200000...00000[-499]. Donc je redéfinis addzeros en needzeroes. Si on appelle sous la forme *\XINTinFloatS*, on ne fait pas l'addition de zeros.

```
2094 \def\XINT_infloat_sp_needzeros #1.#2.#3.#4.{!#1.#2[#4]}%
```

L-P=#1.A=#2#3.P=#4.N=#5.

Ici P<L. Il va falloir arrondir. Attention si on va à la puissance de 10 suivante. En #1 on a L-P qui est >0. L'exposant final sera N+L-P, sauf dans le cas spécial, il sera alors N+L-P+1. L'ajustement final est fait par *\XINT_infloat_Y*.

```

input v.B''.junk.|B|.u.A''.P.|A|.n.{A}{B}
output Q1.P.|B|.|A|.n.{A}{B}
Q1 = division euclidienne de A''.10^{u-v+P+3} par B''.
Special detection of cases with A and B both having length at most P+4: this will happen when
called from \xintFloatDiv as A and B (produced then via \XINTinFloatS) will have at most P digits.
We then only need integer division with P+1 extra zeros, not P+3.

8.71 \xintPFloat

1.1. This is a prettifying printing macro for floats.

The macro applies one simple rule: $x.yz...eN$ will drop scientific notation in favor of pure decimal notation if $-5 \leq N \leq 5$. This is the default behaviour of Maple. The N here is as produced on output by *\xintFloat*.

Special case: the zero value is printed 0. (with a dot)

The coding got simpler with 1.2k as its *\xintFloat* always produces a mantissa with exactly P digits (no more 10.0...0eN annoying exception).

```

8.72 \XINTinFloatFracdigits

1.09i, for *frac* function in *\xintfloatexpr*. This version computes exactly from the input the fractional part and then only converts it into a float with the asked-for number of digits. I will have to think it again some day, certainly.

1.1 removes optional argument for which there was anyhow no interface, for technical reasons having to do with *\xintNewExpr*.

1.1a renames the macro as *\XINTinFloatFracdigits* (from *\XINTinFloatFrac*) to be synchronous with the *\XINTinFloatSqrt* and *\XINTinFloat* habits related to *\xintNewExpr* problems.

Note to myself: I still have to rethink the whole thing about what is the best to do, the initial way of going through *\xinttfrac* was just a first implementation.

```

```

8.73 \xintFloatAdd, \XINTinFloatAdd

First included in release 1.07.

1.09ka improved a bit the efficiency. However the *add*, *sub*, *mul*, *div* routines were provisory and supposed to be revised soon.

Which didn't happen until 1.2f. Now, the inputs are first rounded to P digits, not P+2 as earlier.

8.75 **\xintFloatMul**, **\XINTinFloatMul**

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via *\XINTinFloatS* which will be more efficient when the precision is large and the input is for example a small constant like 2.

1.2k does a micro improvement to the way the macro passes over control to its output routine (former version used a higher level *\xintE* causing some extra un-needed processing with two calls to *\XINT_infrac* where one was amply enough).

```

```

8.78 **\xintFloatPow**, **\XINTinFloatPow**

1.07: initial version. 1.09j has re-organized the core loop.

2015/12/07. I have hesitated to map $^$ in expressions to *\xintFloatPow* rather than *\xintFloatPower*. But for 1.234567890123456 to the power 2145678912 with P=16, using Pow rather than Power seems to bring only about 5% gain.

This routine requires the exponent x to be compatible with \numexpr parsing.

1.2f has rewritten the code for better efficiency. Also, now the argument A for A^x is first rounded to P digits before switching to the increased working precision (which depends upon x).

This ending is common with *\xintFloatPower*.

In the case of negative exponent we need to inverse the Q-digits mantissa. This requires no special attention now as 1.2k's *\xintFloat* does correct rounding of fractions hence it is easy to bound the total error. It can be checked that the algorithm after final rounding to the target precision computes a value Z whose distance to the exact theoretical will be less than 0.52 ulp(Z) (and worst cases can only be slightly worse than 0.51 ulp(Z)).

In the case of the half-integer exponent (only via the expression interface,) the computation (which proceeds via *\XINTinFloatPowerH*) ends with a square root. This square root extraction is done with 3 guard digits (the power operations were done with more.) Then the value is rounded to the target precision. There is thus this rounding to 3 guard digits (in the case of negative exponent the reciprocal is computed before the square-root), then the square root is (computed with exact rounding for these 3 guard digits), and then there is the final rounding of this to the target precision. The total error (for positive as well as negative exponent) has been estimated to at worst possibly exceed slightly 0.5125 ulp(Z), and at any rate it is less than 0.52 ulp(Z).

8.79 *\xintFloatPower*, *\XINTinFloatPower*

1.07. The core loop has been re-organized in 1.09j for some slight efficiency gain. The exponent B is given to *\xintNum*. The ^ in expressions is mapped to this routine.

Same modifications as in *\xintFloatPow* for 1.2f.

1.2f adds a special private macro for allowing half-integral exponents for use with ^ within *\xintfloatexpr*. The exponent will be first truncated to either an integer or an half-integer. The macro is not for general use.

1.2k does anew this 1.2f handling of half-integer exponents for the *\xintfloatexpr* parser: with 1.2f's code the final square-root extraction was applied to a value already rounded to the target precision, unneedlessly losing precision.

```

2593 \def\xintFloatPower {\romannumeral0\xintfloatpower}%
2594 \def\xintfloatpower #1{\XINT_flpower_chkopt \xintfloat #1\xint:}%

2596 \def\XINTinfloatpower #1{\XINT_flpower_chkopt \XINTinfloatS #1\xint:}%

```

First the special macro for use by the expression parser which checks if one raises to an half-integer exponent. This is always with *\XINT*digits precision. Rewritten for 1.2k in order for the final square root to keep three guard digits.

We have to be careful that exponent #2 is not constrained by TeX bound. And we must allow fractions. The 1.2k variant does a rounding to nearest integer of half-integer, 1.2f did a truncation rather (this is done after truncation of #2 to fixed point with one digit after mark.) We try to recognize quickly the case of integer exponent, for speed, but there is overhead of going through *\xintiTrunc1*.

Computations are done with Q blocks of eight digits. When a multiplication has a carry, hence creates Q+1 blocks, the least significant one is dropped. The goal is to compute an approximate value X' to the exact value X , such that the final relative error $(X-X')/X$ will be at most 10^{-P-1} with P the desired precision. Then, when we round X' to X'' with P significant digits, we can prove that the absolute error $|X-X''|$ is bounded (strictly) by 0.6 ulp(X''). (ulp= unit in the last (significant) place). Let N be the number of such operations, the formula for Q deduces from the previous explanations is that $8Q$ should be at least $P+9+k$, with k the number of digits of N (in base 10). Note that 1.2 version used $P+10+k$, for 1.2f I reduced to $P+9+k$. Also, k should be the number of digits of the number N of multiplications done, hence for $n \leq 10000$ we can take $N=n/2$, or $N/3$, or $N/4$. This is rounded above by numexpr and always an overestimate of the actual number of approximate multiplications done (the first ones are exact). (vérifier ce que je raconte, j'ai la flemme là).

We then want $\text{ceil}((P+k+n)/8)$. Using \numexpr rounding division (ARRRRRGHHHHH), if m is a positive integer, $\text{ceil}(m/8)$ can be computed as $(m+3)/8$. Thus with $m=P+10+k$, this gives $Q < -(P+13+k)/8$. The routine actually computes $8(Q-1)$ for use in \XINT_FL_fac_addzeros.

With 1.2f the formula is $m=P+9+k$, $Q < -(P+12+k)/8$, and we use now $4=12-8$ rather than the earlier $5=13-8$. Whatever happens, the value computed in \XINT_FL_fac_increaseP is at least 8. There will always be an extra block.

Note: with Digits:=32; Maple gives for 200!:

```

> factorial(200.);
375
0.78865786736479050355236321393218 10

```

My 1.2f routine (and also 1.2) outputs:

7.8865786736479050355236321393219e374

and this is the correct rounding because for 40 digits it computes

7.886578673647905035523632139321850622951e374

Maple's result (contrarily to *xint*) is thus not the correct rounding but still it is less than 0.6 ulp wrong.

This is the crucial ending. I note that I used here an `\ifnum` test rather than the `gob_til_eightzeroes` thing. Actually for eight digits there is much less difference than for only four.

The "carry" situation is marked by a final `!-1` rather than `!-2` for no-carry. (a `\numexpr` must be stopped, and leaving a `-` as delimiter is good as it will not arise earlier.)

8.81 `\xintFloatPFactorial`, `\XINTinFloatPFactorial`

2015/11/29 for 1.2f. Partial factorial `pfactorial(a,b)=(a+1)...b`, only for non-negative integers with $a \leq b < 10^8$.

1.2h (2016/11/20) now avoids raising `\xintError:OutOfRangePFac` if the condition $0 \leq a \leq b < 10^8$ is violated. Same as for `\xintiiPFactorial`.

See the comments for `\xint_FL_pfac_increaseP`. Case of $b=a+1$ should be filtered out perhaps. We only needed here to copy the `\xintPfactorial` macros and re-use `\xint_FL_fac_mul`/`\xint_FL_fac_out`. Had to modify a bit `\xint_FL_pfac_addzeroes`. We can enter here directly with `#3` equal to specify the precision (the calculated value before final rounding has a relative error less than $\#3.10^{-\#4-1}$), and `#5` would hold the macro doing the final rounding (or truncating, if I make a `FloatTrunc` available) to a given number of digits, possibly not `#4`. By default the `#3` is 1, but `FloatBinomial` calls it with `#3=4`.

8.82 *\xintFloatBinomial*, *\XINTinFloatBinomial*

1.2f. We compute *binomial(x,y)* as *pfac(x-y,x)/y!*, where the numerator and denominator are computed with a relative error at most 4.10^{-P-2} , then rounded (once I have a float truncation, I will use truncation rather) to $P+3$ digits, and finally the quotient is correctly rounded to P digits. This will guarantee that the exact value X differs from the computed one Y by at most $0.6 \text{ulp}(Y)$. (2015/12/01).

2016/11/19 for 1.2h. As for *\xintiiBinomial*, hard to understand why last year I coded this to raise an error if $y < 0$ or $y > x$! The question of the Gamma function is for another occasion, here *x* and *y* must be (small) integers.

8.83 `\xintFloatSqrt`, `\XINTinFloatSqrt`

First done for 1.08.

The float version was developed at the same time as the integer one and even a bit earlier. As a result the integer variant had some sub-optimal parts. Anyway, for 1.2f I have rewritten the integer variant, and the float variant delegates all preparatory work for it until the last step. In particular the very low precisions are not penalized anymore from doing computations for at least 17 or 18 digits. Both the large and small precisions give quite shorter computation times.

Also, after examining more closely the achieved precision I decided to extend the float version

in order for it to obtain the correct rounding (for inputs already of at most P digits with P the precision) of the theoretical exact value.

Beyond about 500 digits of precision the efficiency decreases swiftly, as is the case generally speaking with *xintcore/xint/xintfrac* arithmetic macros.

Final note: with 1.2f the input is always first rounded to P significant places.

```

8.84 `\xintFloatE`, `\XINTinFloatE`

1.07: The fraction is the first argument contrarily to `\xintTrunc` and `\xintRound`.

1.2k had to rewrite this since there is no more a `\XINT_float_a` macro. Attention about `\XINTinFloatE`: it is for use by `xintexpr.sty`, contrarily to other `\XINTinFloat<foo>` macros it inserts itself the `[\XINTdigits]` thing, and with value 0 it produces on output `0[N]`, not `0[0]`.

```

8.87 \XINTinFloatDivMod

1.2p. Pour emploi dans *xintexpr*, donc je ne prends pas la peine de faire l'expansion du modulo, qui se produira dans le \csname.

Hésitation sur le quotient, faut-il l'arrondir immédiatement ? Finalement non, le produire comme un integer.

Breaking change at 1.4 as output format is not comma separated anymore. Attention also that it uses \expanded.

No time now at the time of completion of the big 1.4 rewrite of *xintexpr* to test whether code efficiency here can be improved to expand the second item of output.

```

```

8.90 \XINTinFloatdigits, \XINTinFloatSqrtdigits, \XINTinFloatFacdigits, \XINTiLogTendigits

For `\xintNewExpr` matters, mainly.

At 1.3e I add `\XINTinFloatSdigits` and use it at various places. I also modified `\XINTinFloatFac` to use S(hort) output format.

Also added `\XINTiLogTendigits`.

This whole stuff moved over from `xintexpr.sty` at 1.4

```
3397 \def\XINTinFloatdigits {\XINTinFloat [\XINTdigits]}%

3399 \def\XINTinFloatSqrtdigits {\XINTinFloatSqrt[\XINTdigits]}%
3400 \def\XINTinFloatFacdigits {\XINTinFloatFac [\XINTdigits]}%
3401 \def\XINTfloatiLogTendigits{\XINTfloatiLogTen[\XINTdigits]}%
```

8.91 (WIP) \XINTinRandomFloatS, \XINTinRandomFloatSdigits

1.3b. Support for `random()` function.

Thus as it is a priori only for `xintexpr` usage, it expands inside `\csname` context, but as we need to get rid of initial zeros we use `\xintRandomDigits` not `\xintXRandomDigits` (`\expanded` would have a use case here).

And anyway as we want to be able to use `random()` in `\xintdeffunc/\xintNewExpr`, it is good to have f-expandable macros, so we add the small overhead to make it f-expandable.

We don't have to be very efficient in removing leading zeroes, as there is only 10% chance for each successive one. Besides we use (current) internal storage format of the type `A[N]`, where `A` is not required to be with `\xintDigits` digits, so `N` will simply be `-\xintDigits` and needs no adjustment.

In case we use in future with #1 something else than `\xintDigits` we do the `0-(#1)` construct.

I had some qualms about doing a random float like this which means that when there are leading zeros in the random digits the (virtual) mantissa ends up with trailing zeros. That did not feel

right but I checked random() in Python (which of course uses radix 2), and indeed this is what happens there.

```
3402 \def\xINTinRandomFloatS{\romannumeral0\xINTinrandomfloatS}%
3403 \def\xINTinRandomFloatSdigits{\XINTinRandomFloatS[\XINTdigits]}%

3438 }%

```

8.94 \PoorManPowerOfTen

1.3f. Transferred from *poormanlog v0.4*. Produces the $10^{\#1}$ with 9 digits of float precision, with an error (believed to be) at most 2 units in the last place. Of course for this the input must be precise enough to have 9 fractional digits of **fixed point** precision.

Attention that this breaks with low level Number too big error if integral part of argument exceeds TeX bound on integers. Indeed some *\numexpr* is used in the code to subtract 8... but anyway *xintfrac* allows for scientific exponents only integers within TeX bounds, so even if it did not break here it would quickly elsewhere.

9.5 \xintPowerSeries

The 1.03 version was very lame and created a build-up of denominators. (this was at a time \xintAdd always multiplied denominators, by the way) The Horner scheme for polynomial evaluation is used in 1.04, this cures the denominator problem and drastically improves the efficiency of the macro. Modified in 1.06 to give the indices first to a \numexpr rather than expanding twice. I just use \the\numexpr and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

9.9 *\xintFxPtPowerSeries*

I am not too happy with this piece of code. Will make it more economical another day. Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a: forgot last time some optimization from the change to *\numexpr*.

```

10 Package *xintcfrac* implementation

.1	Catcodes, ε - \TeX and reload detection	283	.16	\xintiGCtoF	295
.2	Package identification	284	.17	\xintCtoCv , \xintCstoCv	296
.3	\xintCFrac	284	.18	\xintiCstoCv	297
.4	\xintGCFrac	285	.19	\xintGCToCv	297
.5	\xintGGCFrac	287	.20	\xintiGCToCv	299
.6	\xintGCToGCx	288	.21	\xintFtoCv	300
.7	\xintFtoCs	288	.22	\xintFtoCCv	300
.8	\xintFtoCx	289	.23	\xintCntof	300
.9	\xintFtoC	289	.24	\xintGcntoF	301
.10	\xintFtoGC	290	.25	\xintCntoCs	302
.11	\xintFGtoC	290	.26	\xintCntoGC	302
.12	\xintFtoCC	291	.27	\xintGcntoGC	303
.13	\xintCtoF , \xintCstoF	292	.28	\xintCstoGC	304
.14	\xintiCstoF	293	.29	\xintGCToGC	304
.15	\xintGCToF	293			

The commenting is currently (2020/02/19) very sparse. Release 1.09m (2014/02/26) has modified a few things: \xintFtoCs and \xintCntoCs insert spaces after the commas, \xintCstoF and \xintCstoCv authorize spaces in the input also before the commas, \xintCntoCs does not brace the produced coefficients, new macros \xintFtoC , \xintCtoF , \xintCtoCv , \xintFGtoC , and \xintGGCFrac .

There is partial dependency on *xinttools* due to \xintCstoF and \xintCsToCv .

10.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

10.9 \xintFtoC

New in 1.09m: this is the same as \xintFtoCx with empty separator. I had temporarily during preparation of 1.09m removed braces from \xintFtoCx, but I recalled later why that was useful (see doc), thus let's just here do \xintFtoCx {}

10.25 \xintCntoCs

Modified in 1.09m: added spaces after the commas in the produced list. Moreover the coefficients are not braced anymore. A slight induced limitation is that the macro argument should not contain some explicit comma (cf. `\XINT_cntcs_exit_b`), hence `\xintCntoCs {\macro,}` with `\def\macro,#1{<stuff>}` would crash. Not a very serious limitation, I believe.

927 \def\XINT_cntcs_exit_b #1,{ }% romannumeral stopping space already there

```

10.26 \xintCntoGC

Modified in 1.06 to give the N first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that.

1.09m maintains the braces, as the coeff are allowed to be fraction and the slash can not be naked in the GC format, contrarily to what happens in `\xintCntoCs`. Also the separators given to `\xintGCToGCx` may then fetch the coefficients as argument, as they are braced.

11 Package *xintexpr* implementation

This is release 1.4a of 2020/02/19.

Contents

11.1	READ ME! Important warnings and explanations relative to the status of the code source at the time of the 1.4 release	308
11.2	Old comments	309
11.3	Catcodes, ε - \TeX and reload detection	310
11.4	Package identification	311
11.5	<code>\xintDigits*</code> , <code>\xintSetDigits*</code>	311
11.6	Support for output and transform of nested braced contents as core data type	312
11.6.1	Bracketed list rendering with prettifying of leaves from nested braced contents	312
11.6.2	Braced contents rendering via a \TeX alignment with prettifying of leaves	312
11.6.3	Transforming all leaves within nested braced contents	313
11.7	Top level user \TeX interface: <code>\xinteval</code> , <code>\xintfloateval</code> , <code>\xintiieval</code>	314
11.7.1	<code>\xintexpr</code> , <code>\xintiexpr</code> , <code>\xintfloatexpr</code> , <code>\xintiiexpr</code>	314
11.7.2	<code>\XINT_expr_wrap</code> , <code>\XINT_iiexpr_wrap</code> , <code>\XINT_flexpr_wrap</code>	316
11.7.3	<code>\XINTexprprint</code> , <code>\XINTiiexprprint</code> , <code>\XINTflexprprint</code>	316
11.7.4	<code>\xintthe</code> , <code>\xintthealign</code> , <code>\xinttheexpr</code> , <code>\xintthefloatexpr</code> , <code>\xinttheiiexpr</code>	317
11.7.5	<code>\thexintexpr</code> , <code>\thexintiexpr</code> , <code>\thexintfloatexpr</code> , <code>\thexintiiexpr</code>	317
11.7.6	<code>\xintbareeval</code> , <code>\xintbarefloateval</code> , <code>\xintbareiieval</code>	317
11.7.7	<code>\xintthebareeval</code> , <code>\xintthebarefloateval</code> , <code>\xintthebareiieval</code>	318
11.7.8	<code>\xinteval</code> , <code>\xintieval</code> , <code>\xintfloateval</code> , <code>\xintiieval</code>	318
11.7.9	<code>\xintboolexpr</code> , <code>\XINT_boolexpr_print</code> , <code>\xinttheboolexpr</code> , <code>\thexintboolexpr</code>	318
11.7.10	<code>\xintifboolexpr</code> , <code>\xintifboolfloatexpr</code> , <code>\xintifbooliiexpr</code>	318
11.7.11	<code>\xintifsgnexpr</code> , <code>\xintifsgnfloateexpr</code> , <code>\xintifsgniiexpr</code>	318
11.7.12	Small bits we have to put somewhere	319
11.8	Hooks into the numeric parser for usage by the <code>\xintdeffunc</code> symbolic parser	320
11.9	<code>\XINT_expr_getnext</code> : fetch some value then an operator and present them to last waiter with the found operator precedence, then the operator, then the value	320
11.10	<code>\XINT_expr_scan_nbr_or_func</code> : parsing the integer or decimal number or hexa-decimal number or function name or variable name or special hacky things	322
11.10.1	Integral part (skipping zeroes)	323
11.10.2	Fractional part	325
11.10.3	Scientific notation	326
11.10.4	Hexadecimal numbers	327
11.10.5	<code>\XINT_expr_scanfunc</code> : collecting names of functions and variables	329
11.10.6	<code>\XINT_expr_func</code> : dispatch to variable replacement or to function execution	330
11.11	<code>\XINT_expr_op_`</code> : launch function or pseudo-function, or evaluate variable and insert operator of multiplication in front of parenthesized contents	330
11.12	<code>\XINT_expr_op_</code> : replace a variable by its value and then fetch next operator	331
11.13	<code>\XINT_expr_getop</code> : fetch the next operator or closing parenthesis or end of expression	332
11.14	Expansion spanning; opening and closing parentheses	334
11.15	The comma as binary operator	336
11.16	The minus as prefix operator of variable precedence level	337
11.17	The <code>*</code> as Python-like «unpacking» prefix operator	338
11.18	Infix operators	338
11.18.1	<code>&&</code> , <code> </code> , <code><</code> , <code>></code> , <code>==</code> , <code><=</code> , <code>>=</code> , <code>//</code> , <code>/:</code> , <code>+</code> , <code>-</code> , <code>*</code> , <code>/</code> , <code>^</code> , <code>**</code> , <code>'and'</code> , <code>'or'</code> , <code>'xor'</code> , and <code>'mod'</code> .	338
11.18.2	<code>..</code> , <code>..[</code> , and <code>]</code> as infix operators	341

11.18.3	Support macros for .., ..[and]..	342
11.19	Square brackets [] both as a container and a Python slicer	345
11.19.1	[...] as «oneple» constructor	345
11.19.2	[...] brackets and : operator for NumPy-like slicing and item indexing syntax	346
11.19.3	Macro layer implementing indexing and slicing	348
11.20	Support for raw A/B[N]	352
11.21	? as two-way and ?? as three-way «short-circuit» conditionals	352
11.22	! as postfix factorial operator	353
11.23	User defined variables	354
11.23.1	\xintdefvar, \xintdefiivar, \xintdeffloatvar	354
11.23.2	\xintunassignvar	356
11.24	Support for dummy variables	357
11.24.1	\xintnewdummy	357
11.24.2	\xintensuredummy, \xintrestorevariable	358
11.24.3	Checking (without expansion) that a symbolic expression contains correctly nested parentheses	359
11.24.4	Fetching balanced expressions E1, E2 and a variable name Name from E1, Name=E2)	360
11.24.5	Fetching a balanced expression delimited by a semi-colon	360
11.24.6	Low-level support for omit and abort keywords, the break() function, the n++ construct and the semi-colon as used in the syntax of seq(), add(), mul(), iter(), rseq(), iterr(), rrseq(), subsm(), subsn(), ndseq(), ndmap()	360
11.24.7	Reserved dummy variables @, @1, @2, @3, @4, @@, @@(1), ..., @@@, @@@1, ... for recursions	362
11.25	Pseudo-functions involving dummy variables and generating scalars or sequences	363
11.25.1	Comments	363
11.25.2	subs(): substitution of one variable	365
11.25.3	subsm(): simultaneous independent substitutions	365
11.25.4	subsn(): leaner syntax for nesting (possibly dependent) substitutions	366
11.25.5	seq(): sequences from assigning values to a dummy variable	368
11.25.6	iter()	368
11.25.7	add(), mul()	370

11.29.5	Mysterious stuff	398

11.29.6	\XINT_expr_redefinemacros	409
11.29.7	\xintNewExpr, \xintNewIExpr, \xintNewFloatExpr, \xintNewIIExpr	410
11.29.8	\ifxintexprsafecatcodes, \xintexprSafeCatcodes, \xintexprRestoreCatcodes . .	412

11.1 READ ME! Important warnings and explanations relative to the status of the code source at the time of the 1.4 release

At release 1.4 the csname encapsulation of intermediate evaluations during parsing of expressions is dropped, and **xintexpr** requires the \expanded primitive. This means that there is no more impact on the string pool. And as internal storage now uses simply core \TeX{} syntax with braces rather than comma separated items inside a csname dummy control sequence, it became possible to let the [...] syntax be associated to a true internal type of «tuple» or «list».

The output of \xintexpr (after \romannumeral0 or \romannumeral-`0 triggered expansion or double expansion) is thus modified at 1.4. It now looks like this:

```
\XINTfstop \XINTexprprint .{{<number>}} in simplest case
\XINTfstop \XINTexprprint .{{...}}...{{...}} in general case
```

where ... stands for nested braces ultimately ending in {{<num. rep.>}} leaves. The <num. rep.> stands for some internal representation of numeric data. It may be empty, and currently as well as probably in future uses only catcode 12 tokens (no spaces currently).

{}{} corresponds (in input as in output) to []. The external TeX braces also serve as set-theoretical braces. The comma is concatenation, so for example [], [] will become {{}{}{}}, or rather {}{} if sub-unit of something else.

The associated vocabulary is explained in the user manual and we avoid too much duplication here. **xintfrac** numerical macros receiving an empty argument usually handle it as being 0, but this is not the case of the **xintcore** macros supporting \xintiiexpr, they usually break if exercised on some empty argument.

The above expansion result uses thus only normal catcodes are output, i.e. the backslash, regular braces, and catcode 12 characters (scientific notation is internally converted to raw **xintfrac** representation [N]).

Additional data may be located before the dot; this is the case only for \xintfloatexpr currently. As **xintexpr** actually defines three parsers \xintexpr, \xintiiexpr and \xintfloatexpr but tries to share as much code as possible, some overhead is induced to fit all into the same mold.

\XINTfstop stops \romannumeral-`0 (or 0) type spanned expansion, and is invariant under \edef, but simply disappears in typesetting context. It is thus now legal to use \xintexpr directly in typesetting flow.

\XINTexprprint is \protected.

The f-expansion of an \xintexpr <expression>\relax is a complete expansion, i.e. one whose result remains invariant under \edef. But if exposed to finitely many expansion steps (at least two) there is a «blinking» \noexpand upfront depending on parity of number of steps.

\xintthe\xintexpr <expression>\relax or \xinteval{<expression>} serve as formerly to deliver the explicit digits, or more exactly some prettifying view of the actual <internal number representation>. For example \xintthe\xintboolexpr will (this is tentative) use True and False in output.

Nested contents like this

```
{1}{2}{3}{4}{5}{6}}{9}}
```

will get delivered using nested square brackets like that

```
1, [2, 3, [4, 5, 6]], 9
```

and as conversely \xintexpr 1, [2, 3, [4, 5, 6]], 9\relax expands to

```
\XINTfstop \XINTexprprint .{1}{2}{3}{4}{5}{6}}{9}}
```

we obtain the gratifying result that

```
\xinteval{1, [2, 3, [4, 5, 6]], 9}
```

expands to

1, [2, 3, [4, 5, 6]], 9

See user manual for explanations on the plasticity of \xintexpr syntax regarding functions with multiple arguments, and the 1.4 «unpacking» Python-like * prefix operator.

I have suppressed (from the public dtx) many big chunks of comments. Some became obsolete and need to be updated, others are currently of value only to the author as a historical record.

ATTENTION! As the removal process itself took too much time, I ended up leaving as is many comments which are obsoleted and wrong to various degrees after the 1.4 release. Precedence levels of operators have all been doubled to make room for new constructs

Even comments added during 1.4 developement may now be obsolete because the preparation of 1.4 took a few weeks and that's enough of duration to provide the author many chances to contradict in the code what has been already commented upon.

Thus don't believe (fully) anything which is said here!

Warning: in text below and also in left-over old comments I may refer to «until» and «op» macros; due to the change of data storage at 1.4, I needed to refactor a bit the way expansion is controlled, and the situation now is mainly governed by «op», «exec», «check» and «checkp» macros the latter three replacing the two «until_a» and «until_b» of former code. This allows to diminish the number of times an accumulated result will be grabbed in order to propagate expansion to its right. Formerly this was not an issue because such things were only a single token! I do not describe here how this is all articulated but it is not hard to see it from the code (the hardest thing in all such matter was in 2013 to actually write how the expansion would be intially launched becasue to do that one basically has to understand the mechanism in its whole and such things are not easy to develop piecemeal). Another thing to keep in mind is that operators in truth have a left precedence (i.e. the precedence they show to operators arising earlier) and a right precedence (which determines how they react to operators coming after them from the right). Only the first one is usually encapsulated in a chardef, the second one is most of the times identical to the first one and if not it is only virtual but implemented via \ifcase of \ifnum branching. A final remark is that some things are achieved by special «op» macros, which are a favorite tool to hack into the normal regular flow of things, via injection of special syntax elements. I did not rename these macros for avoiding too large git diffs, and besides the nice thing is that the 1.4 refactoring minimally had to modify them, and all hacky things using them kept on working with not a single modification. And a post-scriptum is that advanced features crucially exploit injecting sub-\xintexpr-essions, as all is expandable there is no real «context» (only a minimal one) which one would have to perhaps store and restore and doing this sub-expression injection is rather cheap and efficient operation.

11.2 Old comments

These general comments were last updated at the end of the 1.09x series in 2014. The principles remain in place to this day but refer to [CHANGES.html](#) for some significant evolutions since.

The first version was released in June 2013. I was greatly helped in this task of writing an expandable parser of infix operations by the comments provided in [13fp-parse.dtx](#) (in its version as available in April-May 2013). One will recognize in particular the idea of the 'until' macros; I have not looked into the actual [13fp](#) code beyond the very useful comments provided in its documentation.

A main worry was that my data has no a priori bound on its size; to keep the code reasonably efficient, I experimented with a technique of storing and retrieving data expandably as *names* of control sequences. Intermediate computation results are stored as control sequences `\.=a/b[n]`.

Roughly speaking, the parser mechanism is as follows: at any given time the last found ``operator'' has its associated *until* macro awaiting some news from the token flow; first *getnext* expands forward in the hope to construct some number, which may come from a parenthesized sub-expression,

from some braced material, or from a digit by digit scan. After this number has been formed the next operator is looked for by the `getop` macro. Once `getop` has finished its job, `until` is presented with three tokens: the first one is the precedence level of the new found operator (which may be an end of expression marker), the second is the operator character token (earlier versions had here already some macro name, but in order to keep as much common code to `expr` and `floatexpr` common as possible, this was modified) of the new found operator, and the third one is the newly found number (which was encountered just before the new operator).

The `until` macro of the earlier operator examines the precedence level of the new found one, and either executes the earlier operator (in the case of a binary operation, with the found number and a previously stored one) or it delays execution, giving the hand to the `until` macro of the operator having been found of higher precedence.

A minus sign acting as prefix gets converted into a (unary) operator inheriting the precedence level of the previous operator.

Once the end of the expression is found (it has to be marked by a `\relax`) the final result is output as four tokens (five tokens since `1.09j`) the first one a catcode 11 exclamation mark, the second one an error generating macro, the third one is a protection mechanism, the fourth one a printing macro and the fifth is `\.=a/b[n]`. The prefix `\xintthe` makes the output printable by killing the first three tokens.

11.3 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%

11.6.3 Transforming all leaves within nested braced contents

1.4. Leaves must be of catcode 12... This is currently not a constraint (or rather not a new constraint) for *xintexpr* because formerly anyhow all data went through csname encapsulation and extraction via string.

In order to share code with the functioning of universal functions, which will be allowed to transform a number into an ople, the applied macro is supposed to apply one level of bracing to its output. Thus to apply this with an *xintfrac* macro such as `\xintiRound{0}` one needs first to define a wrapper which will expand it into braces :

```
\def\foo#1{{\xintiRound{0}}{#1}}
```

As the things will expand inside expanded, propagating expansion is not an issue.

This code is used by `\xintieexpr` and `\xintfloatexpr` in case of optional argument and by the «Universal functions».

```

11.7.1 `\xintexpr`, `\xintiexpr`, `\xintfloatexpr`, `\xintiiexpr`

`\xintiexpr` and `\xintfloatexpr` have an optional argument since 1.1.

ATTENTION! 1.3d renamed \xinteval to \xintexpr etc...

The 1.4a version of optional argument [D] for \xintexpr accepts a negative D, with same meaning as \xintTrunc from xintfrac.sty.

11.7.3 *\XINTexprprint*, *\XINTiexprprint*, *\XINTflexprprint*

Comments currently under reconstruction.

1.4: The reason for *\expanded* is to ensure *\xintthe* mechanism does expand completely in two steps, now that the print helper macros are not f-expandable anymore.

It is possible that the expression gave an empty object (e.g. *\xintexpr [4][1]\relax*). Thus we do not use *\romannumeral`^@* trigger else twice expansion of *\xinttheexpr* will propagate beyond empty expression. Thus *\romannumeral* ended via a chardef zero token.

```

11.7.4 \xintthe, \xintthealign, \xinttheexpr, \xinttheiexpr, \xintthefloatexpr, \xinttheiiexpr

The reason why *\xinttheiexpr* et *\xintthefloatexpr* are handled differently is that they admit an optional argument which acts via a custom «printing» stage.

We exploit here that *\expanded* expands forward until finding an implicit or explicit brace, and that this expansion overrules *\protected* macros, forcing them to expand, similarly as *\roman-* numeral expands *\protected* macros, and contrarily to what happens *within* the actual *\expanded* scope. I discovered this fact by testing (with pdftex) and I don't know where this is documented apart from the source code of the relevant engines. This is useful to us because there are contexts where we will want to apply a complete expansion before printing, but in purely numerical context this is not needed (if I converted correctly after dropping at 1.4 the *\csname* governed expansions; however I rely at various places on the fact that the *xint* macros are f-expandable, so I have tried to not use zillions of expanded all over the place), hence it is not needed to add the expansion overhead by default. But the *\expanded* here will allow *\xintNewExpr* to create macro with suitable modification or the printing step, via some hook rather than having to duplicate all macros here with some new «NE» meaning (aliasing does not work or causes big issues due to desire to support *\xinteval* also in «NE» context as sub-constituent. The *\XINT:NEhook:x:toblist* is something else which serves to achieve this support of *sub* *\xinteval*, it serves nothing for the actual produced macros. For *\xintdeffunc*, things are simpler, but still we support the [N] optional argument of *\xintiexpr* and *\xintfloatexpr*, which required some work...).

11.7.12 Small bits we have to put somewhere

Some renaming and modifications here with release 1.2 to switch from using chains of `\romannumeral`0` in order to gather numbers, possibly hexadecimals, to using a `\csname` governed expansion. In this way no more limit at 5000 digits, and besides this is a logical move because the `\xintexpr` parser is already based on `\csname... \endcsname` storage of numbers as one token.

The limitation at 5000 digits didn't worry me too much because it was not very realistic to launch computations with thousands of digits... such computations are still slow with 1.2 but less so now. Chains or `\romannumeral` are still used for the gathering of function names and other stuff which I have half-forgotten because the parser does many things.

In the earlier versions we used the `lockscan` macro after a chain of `\romannumeral`0` had ended gathering digits; this uses has been replaced by direct processing inside a `\csname... \endcsname` and the macro is kept only for matters of dummy variables.

Currently, the parsing of hexadecimal numbers needs two nested `\csname... \endcsname`, first to gather the letters (possibly with a hexadecimal fractional part), and in a second stage to apply `\xintHexToDec` to do the actual conversion. This should be faster than updating on the fly the number (which would be hard for the fraction part...).

\xintthecoords 1.1 Wraps up an even number of comma separated items into pairs of TikZ coordinates; for use in the following way:

`coordinates {\xintthecoords\xintfloatexpr ... \relax}`

The crazyness with the `\csname` and `unlock` is due to TikZ somewhat STRANGE control of the TOTAL number of expansions which should not exceed the very low value of 100 !! As we implemented `\XINT_thecoords_b` in an "inline" style for efficiency, we need to hide its expansions.

Not to be used as `\xintthecoords\xintthefloatexpr`, only as `\xintthecoords\xintfloatexpr` (or `\xintexpr` etc...). Perhaps `\xintthecoords` could make an extra check, but one should not accustom users to too loose requirements!

11.9 `\XINT_expr_getnext`: fetch some value then an operator and present them to last waiter with the found operator precedence, then the operator, then the value

Big change in 1.1, no attempt to detect braced stuff anymore as the [N] notation is implemented otherwise. Now, braces should not be used at all; one level removed, then \romannumeral-`0 expansion.

Refactored at 1.4 to put expansion of `\XINT_expr_getop` after the fetched number, thus avoiding it to have to fetch it (which could happen then multiple times, it was not really important when it was only one token in pre-1.4 `xintexpr`).

Allow `\xintexpr\relax` at 1.4.

Refactored at 1.4 the articulation `\XINT_expr_getnext/XINT_expr_func/XINT_expr_getop`. For some legacy reason the first token picked by `getnext` was soon turned to catcode 12. The next ones after the first were not a priori stringified but the first token was, and this made allowing things such as `\xintexpr\relax`, `\xintexpr,,\relax`, `[], 1+()`, `[:]` etc... complicated and requiring each time specific measures.

```

This is a key component which is involved in:

- support for `\xintdeffunc` via special handling of parameter character,
- support for skipping over ignored + signs,
- support for Python-like * «unpacking» unary operator (added at 1.4),
- support for [...] tuple constructor (1.4, formerly [...] by itself was like (...)),
- support for numbers starting with a decimal point,
- support for the minus as unary operator of variable precedence level,
- support for sub-expressions inside parenthesis (with possibly tacit multiplication)
- else starting the scan of explicit digits or letters for a number or a function name

11.10 \XINT_expr_scan_nbr_or_func: parsing the integer or decimal number or hexa-decimal number or function name or variable name or special hacky things

11.10.1	Integral part (skipping zeroes)	323
11.10.2	Fractional part	325
11.10.3	Scientific notation	326
11.10.4	Hexadecimal numbers	327
11.10.5	<code>\XINT_expr_scanfunc</code> : collecting names of functions and variables	329
11.10.6	<code>\XINT_expr_func</code> : dispatch to variable replacement or to function execution	330

1.2 release has replaced chains of \romannumeral-`0 by \csname governed expansion. Thus there is no more the limit at about 5000 digits for parsed numbers.

In order to avoid having to lock and unlock in succession to handle the scientific part and adjust the exponent according to the number of digits of the decimal part, the parsing of this decimal part counts on the fly the number of digits it encounters.

There is some slight annoyance with `\xintiiexpr` which should never be given a [n] inside its `\csname .=<digits>\endcsname` storage of numbers (because its arithmetic uses the ii macros which know nothing about the [N] notation). Hence if the parser has only seen digits when hitting something else than the dot or e (or E), it will not insert a [0]. Thus we very slightly compromise the efficiency of `\xintexpr` and `\xintfloatexpr` in order to be able to share the same code with `\xintiiexpr`.

Indeed, the parser at this location is completely common to all, it does not know if it is working inside `\xintexpr` or `\xintiiexpr`. On the other hand if a dot or a e (or E) is met, then the (common) parser has no scruples ending this number with a [n], this will provoke an error later if that was within an `\xintiiexpr`, as soon as an arithmetic macro is used.

As the gathered numbers have no spaces, no pluses, no minuses, the only remaining issue is with leading zeroes, which are discarded on the fly. The hexadecimal numbers leading zeroes are stripped in a second stage by the `\xintHexToDec` macro.

With 1.2, `\xinttheexpr . \relax` does not work anymore (it did in earlier releases). There must be digits either before or after the decimal mark. Thus both `\xinttheexpr 1.\relax` and `\xinttheexpr .1\relax` are legal.

The ` syntax is here used for special constructs like `+`(..), `*`(..) where + or * will be treated as functions. Current implementation picks only one token (could have been braced stuff), here it will be + or *, and via \XINT_expr_op_` this then becomes a suitable \XINT_{expr|iiexpr|flexpr}_func_+ (or *). Documentation says to use `+`(...), but `+(...)` is also valid. The opening parenthesis must be there, it is not allowed to come from expansion.

Attention at this location #1 was of catcode 12 in all versions prior to 1.4.

Besides using principally \if tests, we will assume anyhow that catcodes of digits are 12...

```

With 1.2d the tacit multiplication in front of a variable name or function name is now done with a higher precedence, intermediate between the common one of `*` and `/` and the one of `^`. Thus $x/2y$ is like $x/(2y)$, but x^2y is like x^2*y and $2y!$ is not $(2y)!$ but $2*y!$.

Finally, 1.2d has moved away from the `_scan` macros all the business of the tacit multiplication in one unique place via `\XINT_expr_getop`. For this, the ending token is not first given to `\string` as was done earlier before handing over back control to `\XINT_expr_getop`. Earlier we had to identify the catcode 11 ! signaling a sub-expression here. With no `\string` applied we can do it in `\XINT_expr_getop`. As a corollary of this displacement, parsing of big numbers should be a tiny bit faster now.

Extended for 1.2l to ignore underscore character `_` if encountered within digits; so it can serve as separator for better readability.

It is not obvious at 1.4 to support `[]` for three things: packing, slicing, ... and raw `xintfrac` syntax $A/B[N]$. The only good way would be to actually really separate completely `\xintexpr`, `\xintfloatexpr` and `\xintiexpr` code which would allow to handle both `/` and `[]` from $A/B[N]$ as we handle `e` and `E`. But triplicating the code is something I need to think about. It is not possible as in pre 1.4 to consider `[` only as an operator of same precedence as multiplication and division which was the way we did this, but we can use the technique of fake operators. Thus we intercept hitting a `[` here, which is not too much of a problem as anyhow we dropped temporarily $3*[1,2,3]+5$ syntax so we don't have to worry that $3[1,2,3]$ should do tacit multiplication. I think only way in future will be to really separate the code of the three parsers (or drop entirely support for $A/B[N]$; as 1.4 has modified output of `\xinteval` to not use this notation this is not too dramatic).

Anyway we find a way to inject here the former handling of `[N]`, which will use a delimited macro to directly fetch until the closing`]`. We do still need some fake operator because $A/B[N]$ is (A/B) times 10^N and the `/B` is allowed to be missing. We hack this using the `which` is not used currently as operator elsewhere in the syntax and need to hook into `\XINT_expr_getop_b`. No finally I use the null char. It must be of catcode 12.

11.10.4 Hexadecimal numbers

1.2d has moved most of the handling of tacit multiplication to `\XINT_expr_getop`, but we have to do some of it here, because we apply `\string` before calling `\XINT_expr_scanhexI_aa`. I do not insert the `*` in `\XINT_expr_scanhexI_a`, because it is its higher precedence variant which will be expected, to do the same as when a non-hexadecimal number prefixes a sub-expression. Tacit multiplication in front of variable or function names will not work (because of this `\string`).

Extended for 1.21 to ignore underscore character `_` if encountered within digits.

```

11.10.5 `\XINT_expr_scanfunc`: collecting names of functions and variables

At 1.4 the first token left over in string has not been submitted to `\string`. We also know it is not a control sequence. So we can test catcode to identify if operator is found. And it is allowed to hit some operator such as a closing parenthesis we will then insert the «nil» value (which however can cause breakage of arithmetic operations, although *xintfrac.sty* converts empty to 0).

The @ causes a problem because it must work with both catcode 11 or 12.

The _ can be used internally for starting variables but it will have catcode 11 then.

There was prior to 1.4 solely the dispatch in `\XINT_expr_scanfunc_b` but now we do it immediately and issue `\XINT_expr_func` only in certain cases.

But we have to be careful that `!(...)` and `?(...)` are part of the syntax and genuine functions. Because we now do earlier to getop we must filter them out.

```

```

This handles: 1) (indirectly) tacit multiplication by a variable in front a of sub-expression, 2) (indirectly) tacit multiplication in front of a `\count` etc..., 3) functions which are recognized via an encountered opening parenthesis (but later this must be disambiguated from variables with tacit multiplication) 4) 5) 6) 7) acceptable components of a variable or function names: @, underscore, digits, letters (or chars of category code letter.)

The short lived 1.2d which followed the even shorter lived 1.2c managed to introduce a bug here as it removed the check for catcode 11 !, which must be recognized if ! is not to be taken as part of a variable name. Don't know what I was thinking, it was the time when I was moving the handling of tacit multiplication entirely to the `\XINT_expr_getop` side. Fixed in 1.2e.

I almost decided to remove the `\ifcat\relax` test whose rôle is to avoid the `\string#1` to do something bad is the escape char is a digit! Perhaps I will remove it at some point ! I truly almost did it, but also the case of no escape char is a problem (`\string\0`, if `\0` is a count ...)

The (indirectly) above means that via `\XINT_expr_func` then `\XINT_expr_op_` one goes back to `\XINT_expr_getop` then `\XINT_expr_getop_b` which is the location where tacit multiplication is now centralized. This makes the treatment of tacit multiplication for situations such as `<variable>\count` or `<variable>\xintexpr..\relax`, perhaps a bit sub-optimal, but first the variable name must be gathered, second the variable must expand to its value.

11.10.6 `\XINT_expr_func`: dispatch to variable replacement or to function execution

Comments written 2015/11/12: earlier there was an `\ifcsname` test for checking if we had a variable in front of a `(`, for tacit multiplication for example in `x(y+z(x+w))` to work. But after I had implemented functions (that was yesterday...), I had the problem if was impossible to re-declare a variable name such as "f" as a function name. The problem is that here we can not test if the function is available because we don't know if we are in `expr`, `iiexpr` or `floatexpr`. The `\xint_c_ii^v` causes all fetching operations to stop and control is handed over to the routines which will be `expr`, `iiexpr` ou `floatexpr` specific, i.e. the `\XINT_{expr|iiexpr|flexpr}_op_{`|_}` which are invoked by the `until_<op>_b` macros earlier in the stream. Functions may exist for one but not the two other parsers. Variables are declared via one parser and usable in the others, but naturally `\xintiiexpr` has its restrictions.

Thinking about this again I decided to treat a priori cases such as `x(...)` as functions, after having assigned to each variable a low-weight macro which will convert this into `_getop\.=<value of x>*(...)`. To activate that macro at the right time I could for this exploit the "onliteral" intercept, which is parser independent (1.2c).

This led to me necessarily to rewrite partially the `seq`, `add`, `mul`, `subs`, `iter` ... routines as now the variables fetch only one token. I think the thing is more efficient.

1.2c had `\def\XINT_expr_func #1(#2{\xint_c_ii^v #2[#1]}`

In `\XINT_expr_func` the `#2` is `_` if `#1` must be a variable name, or `#2=`` if `#1` must be either a function name or possibly a variable name which will then have to be followed by tacit multiplication before the opening parenthesis.

The `\xint_c_ii^v` is there because `_op_`` must know in which parser it works. Dispensious for `_`. Hence I modify for 1.2d.

```
698 \def\XINT_expr_func #1(#2{\if _#2\xint_dothis{\XINT_expr_op_{#1}}\fi
699           \xint_orthat{{#1}\xint_c_ii^v #2}}%)
```

11.11 `\XINT_expr_op_``: launch function or pseudo-function, or evaluate variable and insert operator of multiplication in front of parenthesized contents

The "onliteral" intercepts is for `bool`, `togl`, `protect`, ... but also for `add`, `mul`, `seq`, etc... Genuine functions have `expr`, `iiexpr` and `flexpr` versions (or only one or two of the three).

With 1.2c "onliteral" is also used to disambiguate a variable followed by an opening parenthesis from a function and then apply tacit multiplication. However as I use only a \ifcsname test, in order to be able to re-define a variable as function, I move the check for being a function first. Each variable name now has its onliteral_<name> associated macro. This used to be decided much earlier at the time of \XINT_expr_func.

The advantage of 1.2c code is that the same name can be used for a variable or a function.

11.12 \XINT_expr_op__: replace a variable by its value and then fetch next operator

The 1.1 mechanism for \XINT_expr_var_<varname> has been modified in 1.2c. The <varname> associated macro is now only expanded once, not twice. We arrive here via \XINT_expr_func.

At 1.4 \XINT_expr_getop is launched with accumulated result on its left. But the omit and abort keywords are implemented via dummy variables which rely on possibility to modify upstream tokens. If we did here something such as _var_#1\expandafter\endcsname\romannumerical`^^@\XINT_expr_getop the premature expansion of getop would break things. Thus we revert to former code which put \XINT_expr_getop (call it _legacy) in front of variable expansion (in xintexpr < 1.4 this expanded to a single token so the overhead was not serious).

Abusing variables to manipulate token stream is a bit bad, usually I prefer functions for this (such as the break() function) but then I have define 3 macros for the 3 parsers.

The situation here is not satisfactory. But 1.4 has to be released now.

11.13 \XINT_expr_getop: fetch the next operator or closing parenthesis or end of expression

Release 1.1 implements multi-character operators.

1.2d adds tacit multiplication also in front of variable or functions names starting with a letter, not only a @ or a _ as was already the case. This is for $(x+y)z$ situations. It also applies higher precedence in cases like $x/2y$ or $x/2@$, or $x/2\max(3,5)$, or $x/2\xintexpr 3\relax$.

In fact, finally I decide that all sorts of tacit multiplication will always use the higher precedence.

Indeed I hesitated somewhat: with the current code one does not know if \XINT_expr_getop as invoked after a closing parenthesis or because a number parsing ended, and I felt distinguishing the two was unneeded extra stuff. This means cases like $(a+b)/(c+d)(e+f)$ will first multiply the last two parenthesized terms.

The ! starting a sub-expression must be distinguished from the post-fix ! for factorial, thus we must not do a too early \string. In versions < 1.2c, the catcode 11 ! had to be identified in all branches of the number or function scans. Here it is simply treated as a special case of a letter.

1.2q adds tacit multiplication in cases such as $(1+1)3$ or $5!7!$

1.4 has simplified coding here as \XINT_expr_getop expansion happens at a time when a fetched value has already being stored.

11.14 Expansion spanning; opening and closing parentheses

These comments apply to all definitions coming next relative to execution of operations from parsing of syntax.

Refactored (and unified) at 1.4. In particular the 1.4 scheme uses *op*, *exec*, *check-*, and *checkp*. Formerly it was *until_a* (*check-*) and *until_b* (now split into *checkp* and *exec*).

This way neither *check-* nor *checkp* have to grab the accumulated number so far (top of stack if you like) and besides one never has to go back to *check-* from *checkp* (and neither from *check-*).

Prior to 1.4, accumulated intermediate results were stored as one token, but now we have to use *\expanded* to propagate expansion beyond possibly arbitrary long braced nested data. With the 1.4 refactoring we do this only once and only grab a second time the data if we actually have to act upon it.

Version 1.1 had a hack inside the *until* macros for handling the *omit* and *abort* in iterations over dummy variables. This has been removed by 1.2c, see the subsection where *omit* and *abort* are discussed.

Exceptionally, the *check-* is here abbreviated to *check*.

11.17 The * as Python-like «unpacking» prefix operator

New with 1.4. Prior to 1.4 the internal data structure was the one of `\csname` encapsulated comma separated numbers. No hierarchical structure was (easily) possible. At 1.4, we can use TeX braces because there is no detokenization to catcode 12.

```

11.18.3 Support macros for .., ..[and].

\xintSeq:tl:x Commence par remplacer a par ceil(a) et b par floor(b) et renvoie ensuite les entiers entre les deux, possiblement en décroissant, et extrémités comprises. Si a=b est non entier en obtient donc ceil(a) et floor(a). Ne renvoie jamais une liste vide.

Note: le a..b dans \xintfloatexpr utilise cette routine.

\xintSeqB:tl:x At 1.4, delayed expansion of start and step done here and not before, for matters of *\xintdeffunc* and «NEhooks».

The float variant at 1.4 is made identical to the exact variant. I.e. stepping is exact and comparison to the range limit too. But recall that a/b input will be converted to a float. To handle 1/3 step for example still better to use *\xintexpr 1..1/3..10\relax* for example inside the *\xintfloateval*.

11.19 Square brackets [] both as a container and a Python slicer

Refactored at 1.4

The architecture allows to implement separately a «left» and a «right» precedence and this is crucial.

11.19.1 [...] as «oneple» constructor	345
11.19.2 [...] brackets and : operator for NumPy-like slicing and item indexing syntax	346
11.19.3 Macro layer implementing indexing and slicing	348

11.19.1 [...] as «oneple» constructor

In the definition of `\XINT_expr_op_oBracket` the parameter is trash `{}`. The `[` is intercepted by the `getnextfork` and handled via the `\xint_c_ii^v` highest precedence trick to get `op_oBracket` executed.

```

11.19.2 [...] brackets and : operator for NumPy-like slicing and item indexing syntax

The opening bracket [for the ntuple constructor is filtered out by \XINT_expr_getnextfork and becomes «obracket» which behaves with precedence level 2. For the [...] Python slicer on the other hand, a real operator [is defined with precedence level 4 (it must be higher than precedence level of commas) on its right and maximal precedence on its left.

Important: although slicing and indexing shares many rules with Python/NumPy there are some significant differences: in particular there can not be any out-of-range error generated, slicing applies also to «oples» and not only to «ntuple», and nested lists do not have to have their leaves at a constant depth. See the user manual.

Currently, NumPy-like nested (basic) slicing is implemented, i.e [a:b, c:d, N, e:f, M] type syntax with Python rules regarding negative integers. This is parsed as an expression and can arise from expansion or contain calculations.

Currently stepping, Ellipsis, and simultaneous multi-index extracting are not yet implemented. There are some subtle things here with possibility of variables been passed by reference.

At 1.4 the `getnext`, `scanint`, `scanfunc`, `getop` chain got revisited to trigger automatic insertion of the `nil` variable if needed, without having in situations like here to define operators to support «`[:]` or «`:]`». And as we want to implement nested slicing à la NumPy, we would have had to handle also «`:,`» for example. Thus here we simply have to define the sole operator «`:,`» and it will be some sort of inert joiner preparing a slicing spec.

11.19.3 Macro layer implementing indexing and slicing

xintexpr applies slicing not only to «objects» (which can be passed as arguments to functions) but also to «oples».

Our «lists» are not necessarily regular N-dimensional arrays à la NumPy. Leaves can be at arbitrary depths. If we were handling regular «ndarrays», we could proceed a bit differently.

For the related explanations, refer to the user manual.

Notice that currently the code uses f-expandable (and not using \expanded) macros *\xintApply*, *\xintApplyUnbraced*, *\xintKeep*, *\xintTrim*, *\xintNthOne* from *xinttools*.

But the whole expansion happens inside an \expanded context, so possibly some gain could be achieved with x-expandable variants (*xintexpr* < 1.4 had an *\xintKeep:x:csv*).

I coded *\xintApply:x* and *\xintApplyUnbraced:x* in *xinttools*. Brief testing indicated they were perhaps a bit better for 5x5x5x5 and 15x15x15x15 arrays of 8 digits numbers and for 30x30x15 with 16 digits numbers: say 1% gain... this seems to raise to between 4% and 5% for 400x400 array of 1 digit...

Currently sticking with old macros.

\xintNthElt from *xinttools* (knowingly) strips one level of braces when fetching kth «item» from {v1}...{vN}. If we expand {\xintNthElt{k}{{v1}...{vN}}} (notice external braces):

- if k is out of range we end up with {}
- if k is in range and the kth braced item was {} we end up with {}
- if k is in range and the kth braced item was {17} we end up with {17}

Problem is that individual numbers such as 17 are stored {{17}}. So we must have one more brace pair and in the first two cases we end up with {{}}. But in the first case we should end up with the empty ople {}, not the empty bracketed ople {{}}.

I have thus added \xintNthOne to *xinttools* which does not strip brace pair from an extracted item.

Attention: \XINT_nthonepy_a does no expansion on second argument. But here arguments are either numerical or already expanded. Normally.

```

The macros here are basically f-expandable and use the f-expandable \xintKeep and \xintTrim. Prior to *xint* 1.4, there was here an x-expandable \xintKeep:x:csv dealing with comma separated items, for time being we make do with our f-expandable toolkit.

11.20 Support for raw A/B[N]

Releases earlier than 1.1 required the use of braces around A/B[N] input. The [N] is now implemented directly. *BUT* this uses a delimited macro! thus N is not allowed to be itself an expression (I could add it...). *\xintE*, *\xintiiE*, and *\XINTinFloatE* all put #2 in a *\numexpr*. But attention to the fact that *\numexpr* stops at spaces separating digits: *\the\numexpr 3 + 7 9\relax* gives 109 \relax !! Hence we have to be careful.

\numexpr will not handle catcode 11 digits, but adding a *\detokenize* will suddenly make illicite for N to rely on macro expansion.

At 1.4, [is already overloaded and it is not easy to support this. We do this by a kludge maintaining more or less former (very not efficient) way but using \$ sign which is free for time being. No, finally I use the null character, should be safe enough! (I hesitated about using R with catcode 12).

As for ? operator we needed to hack into *\XINT_expr_getop_b* for intercepting that pseudo operator. See also *\XINT_expr_scanint_c* (*\XINT_expr_rawxintfrac*).

11.23 User defined variables

11.23.1 \xintdefvar, \xintdefiivar, \xintdeffloatvar	354
11.23.2 \xintunassignvar	356

11.23.1 \xintdefvar, \xintdefiivar, \xintdeffloatvar

1.1.

1.2p (2017/12/01). extends `\xintdefvar` et al. to accept simultaneous assignments to multiple variables.

1.3c (2018/06/17). Use `\xintexprSafeCatcodes` (to palliate issue with active semi-colon from Babel+French if in body of a \TeX document).

And allow usage with both syntaxes `name:=expr;` or `name=expr;`. Also the colon may have catcode 11, 12, or 13 with no issue. Variable names may contain letters, digits, underscores, and must not start with a digit. Names starting with `@` or an underscore are reserved.

- currently `@`, `@1`, `@2`, `@3`, and `@4` are reserved because they have special meanings for use in iterations,
- `@@`, `@@@`, `@@@@` are also reserved but are technically functions, not variables: a user may possibly define `@@` as a variable name, but if it is followed by parentheses, the function interpretation will be applied (rather than the variable interpretation followed by a tacit multiplication),
- since 1.2l, the underscore `_` may be used as separator of digits in long numbers. Hence a variable whose name starts with `_` will not play well with the mechanism of tacit multiplication of variables by numbers: the underscore will be removed from input stream by the number scanner, thus creating an undefined or wrong variable name, or none at all if the variable name was an initial `_` followed by digits.

Note that the optional argument `[P]` as usable with `\xintfloatexpr` is **not** supported by `\xintdeffloatvar`. One must do `\xintdeffloatvar foo = \xintfloatexpr[16] blabla \relax;` to achieve the effect.

1.4 (2020/01/27). The expression will be fetched up to final semi-colon in a manner allowing inner semi-colons as used in the `iter()`, `rseq()`, `subsm()`, `subsn()` etc... syntax. They don't need to be hidden within a braced pair anymore.

TODO: prior to 1.4 a variable «value» was passed along as a single token. Now it is managed, like everything else, as explicit braced contents. But most of the code is ready for passing it along again as a single (braced, now) token again, because all needed `\expanded/\unexpanded` things are in place. However this is «most of the code». I am really eager to get 1.4 released now, because I can't devote more time in immediate future. It is too late to engage into an umpteenth deep refactoring at a time where things work and many new features were added and most aspects of inner working got adapted. However in future it could be that variables holding large data will be managed much faster.

Maybe `SafeCatcodes` was without effect because the colon and the rest are from some earlier macro definition. Give a safe definition to active colon (even if in math mode with a math active colon...).

The `\XINT_expr_defvar_getname` closes the group opened here.

11.23.2 \xintunassignvar

1.2e.

1.3d. Embarrassingly I had for a long time a misunderstanding of `\ifcsname` (let's blame its documentation) and I was not aware that it chooses FALSE branch if tested control sequence has been `\let` to `\undefined`... So earlier version didn't do the right thing (and had another bug: failure to protect `\.=0` from expansion).

The `\ifcsname` tests are done in `\XINT_expr_op_` and `\XINT_expr_op_``.

```

```

11.24.5 Fetching a balanced expression delimited by a semi-colon

1.4. For `subsn()` leaner syntax of nested substitutions.

Will also serve to `\xintdeffunc`, to not have to hide inner semi-colons in for example an `iter()` from `\xintdeffunc`.

Adding brace removal protection for no serious reason, anyhow the `xintexpr` parsers always removes braces when moving forward, but well.

Trigger by `\roman{XINT_expr_fetch_to_semicolon}` upfront.

```

1897 \def\xint_expr_fetch_to_semicolon {\xint_expr_fetch_to_semicolon_a {} \emptyset}%
1898 \def\xint_expr_fetch_to_semicolon_a #1#2;%
1899 {%
1900   \ifcase\xint_isbalanced_a \relax #1#2(\xint_bye)\xint_bye
1901     \xint_dothis{\expandafter\xint_expr_fetch_to_semicolon_c}%
1902   \or\xint_dothis{\expandafter\xint_expr_fetch_to_semicolon_b}%
1903   \else\expandafter\xintError:noopening
1904   \fi\xint_orthat{} \expandafter{#2}{#1}%
1905 }%
1906 \def\xint_expr_fetch_to_semicolon_b #1#2{\xint_expr_fetch_to_semicolon_a {#2#1;} \emptyset}%
1907 \def\xint_expr_fetch_to_semicolon_c #1#2{\xint_c_{#2#1}}%

```

11.24.6 Low-level support for `omit` and `abort` keywords, the `break()` function, the `n++` construct and the semi-colon as used in the syntax of `seq()`, `add()`, `mul()`, `iter()`, `rseq()`, `iterr()`, `rrseq()`, `subsm()`, `subsn()`, `ndseq()`, `ndmap()`

There is some clever play simply based on setting suitable precedence levels combined with special meanings given to op macros.

The special `!?` internal operator is a helper for `omit` and `abort` keywords in list generators.

Prior to 1.4 support for `+[`, `*[`, `...,]+`, `]*`, had some elements here.

The `n++` construct 1.1 2014/10/29 did `\expandafter\.=+\xintiCeil` which transformed it into `\romannumeral0\xinticeil`, which seems a bit weird. This exploited the fact that dummy variables macros could back then pick braced material (which in the case at hand here ended being `\romannumeral0\xinticeil...`) and were submitted to two expansions. The result of this was to provide a not value which got expanded only in the first loop of the `:_A` and following macros of `seq`, `iter`, `rseq`, etc...

Anyhow with 1.2c I have changed the implementation of dummy variables which now need to fetch a single locked token, which they do not expand.

The `\xintiCeil` appears a bit dispendious, but I need the starting value in a `\numexpr` compatible form in the iteration loops.

```
1908 \expandafter\def\csname XINT_expr_itself_++\endcsname {++}%
1909 \expandafter\def\csname XINT_expr_itself_++)\endcsname {++)}%
1910 \expandafter\let\csname XINT_expr_precedence_++)\endcsname \xint_c_i
1911 \xintFor #1 in {expr,fexpr,iiexpr} \do {%
1912     \expandafter\def\csname XINT_#1_op_++)\endcsname ##1##2\relax
1913     {\expandafter\XINT_expr_foundend
1914         \expanded{{+{\XINT:NHook:f:one:from:one:direct\xintiCeil##1}}}}%
1915     }%
1916 }%
```

The `break()` function `break` is a true function, the parsing via expansion of the enclosed material proceeds via `_oparen` macros as with any other function.

```
1917 \catcode`? 3
1918 \def\XINT_expr_func_break #1#2#3{#1#2{?#3}}%
1919 \catcode`? 11

11.25.10	rrseq()	373

11.25.1 Comments

Comments added 2020/01/16.

The mechanism for «seq» is the following. When the parser encounters «seq», which means it parsed these letters and encountered (from expansion) an opening parenthesis, the `\XINT_expr_func` mechanism triggers the «`» operator which realizes that «seq» is a pseudo-function (there is no `_func_seq`) and thus spans the `\XINT_expr_onliteral_seq` macro (currently this means however that the knowledge of which parser we are in is lost, see comments of `\XINT_expr_op_`` code). The latter will use delimited macros and parenthesis check to fetch (without any expansion), the symbolic expression `ExprSeq` to evaluate, the Name (now possibly multi-letter) of the variable and the expression `ExprValues` to evaluate which will give the values to assign to the dummy variable Name. It then positions upstream `ExprValues` suitably terminated (see next) and after it `{[Name]{ExprSeq}}`. Then it inserts a second call to the «`» operator with now «seqx» as argument hence the appropriate «`,fl,ii}expr_func_seqx`» macros gets executed. The general way function macros work is that first all their arguments are evaluated via a call not to `\xintbare{,float,ii}eval` but to the suitable `\XINT_{expr,flexpr,iiexpr}_oparen` core macro which does almost same excepts it expects a final closing parenthesis (of course allowing nested parenthesis in-between) and stops there. Here, this closing parenthesis got positioned deliberately with a `\relax` after it, so the parser, which always after having gathered a value looks ahead to find the next operator, thinks it has hit the end of the expression and as result inserts a `\xint_c_` (i.e. `\z@`) token for precedence level and a dummy `\relax` token (place-holder for a non-existing operator). Generally speaking «`func_foo`» macros expect to be executed with three parameters `#1#2#3`, `#1` = precedence, `#2` = operator, `#3` = values (call it «args») i.e. the fully evaluated list of all its arguments. The special «`func_seqx`» and cousins know that the first two tokens are trash and they now proceed forward, having thus lying before them upstream the values to loop over, now fully evaluated, and `{[Name]{ExprSeq}}`.

It then positions appropriately ExprSeq inside a sub-expression and after it, following suitable delimiter, Name and the evaluated values to assign to Name.

Dummy variables are essentially simply delimited macros where the delimiter is the variable name preceded by a \relax token and a catcode 11 exclamation point. Thus the various «subs», «seqx», «iterx» position the tokens appropriately and launch suitable loops.

All of this nests well, inner «seq»'s (or more often in practice «subs»'s) being allowed to refer to the dummy variables used by outer «seq»'s because the outer «seq»'s have the values to assign to their variables evaluated first and their ExprSeq evaluated last. For inner dummy variables to be able to refer to outer dummy variables the author must be careful of course to not use in the implementation braces { and } which would break dummy variables to fetch values beyond the closing brace.

The above «seq» mechanism was done around June 15-25th 2014 at the time of the transition from 1.09n to 1.1 but already in October 2014 I made a note that I had a hard time to understand it again:

« [START OF YEAR 2014 COMMENTS]

All of seq, add, mul, rseq, etc... (actually all of the extensive changes from xintexpr 1.09n to 1.1) was done around June 15-25th 2014, but the problem is that I did not document the code enough, and I had a hard time understanding in October what I had done in June. Despite the lesson, again being short on time, I do not document enough my current understanding of the innards of the beast...

I added subs, and iter in October (also the [:n], [n:] list extractors), proving I did at least understand a bit (or rather could imitate) my earlier code (but don't ask me to explain \xintNewExpr !)

The \XINT_expr_fetch_E_comma_V_equal_E_a parses: "expression, variable=list)" (when it is called the opening (has been swallowed, and it looks for the ending one.) Both expression and list may themselves contain parentheses and commas, we allow nesting. For example "x^2,x=1..10)", at the end of seq_a we have {variable{expression}}{list}, in this example {x{x^2}}{1..10}, or more complicated "seq(add(y,y=1..x),x=1..10)" will work too. The variable is a single lowercase Latin letter.

The complications with \xint_c_ii^v in seq_f is for the recurrent thing that we don't know in what type of expressions we are, hence we must move back up, with some loss of efficiency (superfluous check for minus sign, etc...). But the code manages simultaneously expr, fexpr and iiexpr.

[END OF YEAR 2014 OLD COMMENTS]»

On Jeudi 16 janvier 2020 à 15:13:32 I finally did the documentation as above.

The case of «iter», «rseq», «iterr», «rrseq» differs slightly because the initial values need evaluation. This is done by genuine functions \XINT_<parser>_func_iter etc... (there was no \XINT_<parser>_func_seq). The trick is via the semi-colon ; which is a genuine operator having the precedence of a closing parenthesis and whose action is only to stop expansion. Thus this first step of gathering the initial values is done as part of the regular expansion job of the parser not using delimited macros and the ; can be hidden in braces {} because the three parsers when moving forward remove one level of braces always. Thus \XINT_<parser>_func_seq simply hand over to \XINT_allexpr_iter which will then trigger the fetching without expansion of ExprIter, Name=ExprValues as described previously for «seq».

With 1.4, multi-letter names for dummy variables are allowed.

Also there is the additional 1.4 ambition to make the whole thing parsable by \xintNewExpr/\xintdeffunc. This is done by checking if all is numerical, because the omit, abort and break() mechanisms have no translation into macros, and the only solution for symbolic material is to simply keep it as is, so that expansion will again activate the xintexpr parsers. At 1.4 this approach is fine although the initial goals of \xintNewExpr/\xintdeffunc was to completely replace the parsers (whose storage method hit the string pool formerly) by macros. Now that 1.4 does not impact the string pool we can make \xintdeffunc much more powerful but it will not be a construct using only xintfrac macros, it will still be partially the \xintexpr etc... parsers in such cases.

Got simpler with 1.2c as now the dummy variable fetches an already encapsulated value, which is anyhow the form in which we get it.

Refactored at 1.4 using \expanded rather than \csname.

And support for multi-letter variables, which means function declarations can now use multi-letter variables !

11.25.2 `subs()`: substitution of one variable

```

1990 \def\XINT_expr_onliteral_subs
1991 {%

```

11.25.3 `subsm()`: simultaneous independent substitutions

New with 1.4. Globally the var1=expr1; var2=expr2; var3=expr3;... part can arise from expansion, except that once a semi-colon has been found (from expansion) the varK= thing following it must be there. And as for `subs()` the final parenthesis must be there from the start.

11.25.6 *iter()*

Prior to 1.2g, the `iter` keyword was what is now called `iterr`, analogous with `rrseq`. Somehow I forgot an `iter` functioning like `rseq` with the sole difference of printing only the last iteration. Both `rseq` and `iter` work well with list selectors, as `@` refers to the whole comma separated sequence of the initial values. I have thus deliberately done the backwards incompatible renaming of `iter` to `iterr`, and the new `iter`.

To understand the tokens which are presented to `\XINT_allexpr_iter` it is needed to check elsewhere in the source code how the ; hack is done.

The #2 in `\XINT_allexpr_iter` is `\xint_c_i` from the ; hack. Formerly (`xint < 1.4`) there was no such token. The change is motivated to using ; also in `subsm()` syntax.

11.25.7 add(), mul()

Comments under reconstruction.

These were a bit anomalous as they did not implement omit and abort keyword and the break() function (and per force then neither the n++ syntax).

At 1.4 they are simply mapped to using adequately iter(). Thus, there is small loss in efficiency, but supporting omit, abort and break is important. Using dedicated macros here would have caused also slight efficiency drop. Simpler to remove the old approach.

```

```

1.4a In case of usage of omit (did I not test it? obviously I didn't as neither omit nor abort could work; and break neither), 1.4 code using (#6) syntax caused a (somewhat misleading) «missing)» error message which originated in the #6. This is non-obvious problem (perhaps explained why prior to 1.4 I had not added support for omit and break() to add() and mul()...).

Allowing () is not enough as it would have to be 0 or 1 depending on whether we are using add() or mul(). Hence the somewhat complicated detour (relying on precise way var OMIT and var_ABORT work) via \xint_allexpr_opx_ifnotomitted.

\break() has special meaning here as it is used as last operand, not as last value. The code is very unsatisfactory and inefficient but this is hotfix for 1.4a.

11.25.8 rseq()

When `func_rseq` has its turn, initial segment has been scanned by `oparen`, the ; mimicking the rôle of a closing parenthesis, and stopping further expansion (and leaving a `xint_c_i` left-over token since 1.4). The ; is discovered during standard parsing mode, it may be for example {;} or arise from expansion as `rseq` does not use a delimited macro to locate it.

```

11.26.3 `ndfillraw()`

New with 1.4. 2020/01/24. J'hésite à autoriser un #1 quelconque, ou plutôt à le wrapper dans un `\xintbareval`. Mais il faut alors distinguer les trois. De toute façon les variables ne marcheraient pas donc j'hésite à mettre un wrapper automatique. Mais ce n'est pas bien d'autoriser l'injection de choses quelconques.

Pour des choses comme `ndfillraw(\xintRandomBit,[10,10])`.

Je n'aime pas le nom !. Le changer. `ndconst?` Surtout je n'aime pas que dans le premier argument il faut rajouter explicitement si nécessaire `\xintiiexpr wrap`.

```

11.27 Other pseudo-functions: `bool()`, `togl()`, `protect()`, `qraw()`, `qint()`, `qfrac()`, `qfloat()`, `qrand()`, `random()`, `rbit()`

`bool`, `togl` and `protect` use delimited macros. They are not true functions, they turn off the parser to gather their "variable".

1.2. adds `qint()`, `qfrac()`, `qfloat()`.

1.3c. adds `qraw()`. Useful to limit impact on \TeX memory from abuse of `\csname`'s storage when generating many comma separated values from a loop.

1.3e. `qfloat()` keeps a short mantissa if possible.

They allow the user to hand over quickly a big number to the parser, spaces not immediately removed but should be harmless in general. The `qraw()` does no post-processing at all apart complete expansion, useful for comma-separated values, but must be obedient to (non really documented) expected format. Each uses a delimited macro, the closing parenthesis can not emerge from expansion.

1.3b. `random()`, `qrand()` Function-like syntax but with no argument currently, so let's use fast parsing which requires though the closing parenthesis to be explicit.

Attention that `qraw()` which pre-supposes knowledge of internal storage model is fragile and may break at any release.

1.4 adds `rbit()`. Short for `random` bit.

Hesitation at 1.3e about using *\XINTinFloatSdigits* and *\XINTinFloatS*. Finally I add a *sfloat()* function. It helps for *xinttrig.sty*.

```

2860     } }%
2861 }%
2862 \let\xint_fexpr_func_float\xint_expr_func_float

```

float_() added at 1.4. Does not check for optional argument. Useful to transfer functions defined with *\xintdeffunc* to functions usable in *\xintfloateval*. I hesitated briefly about notation but here we go. Unfortunately I will have to document it (contrarily to *sqrt_()*).

No need to do same for *sfloat()* currently used in *xinttrig.sty* to go from *float* to *expr*, because *sfloat(x)* sees there is no optional argument.

Still I wonder if better would not be to have some function «*single()*» which signals to outer one it is a single argument? Must think about this. Too late now for 1.4.

```

11.29 User declared functions

It is possible that the author actually does understand at this time the `\xintNewExpr`/`\xintdeffunc` refactored code and mechanisms for the first time since 2014: past evolutions such as the 2018 1.3 refactoring were done a bit in the fog (although they did accomplish a crucial step).

The 1.4 version of function and macro definitions is much more powerful than 1.3 one. But the mechanisms such as «`omit`», «`abort`» and «`break()`» in `iter()` et al. can't be translated into much else than their actual code when they potentially have to apply to non-numeric only context. The 1.4 `\xintdeffunc` is thus apparently able to digest them but its pre-parsing benefits are limited compared to simply assigning such parts of an expression to a mock-function created by `\xintNewFunction` (which creates simply a TeX macro from its substitution expression in macro parameters and add syntactic sugar to let it appear to `\xintexpr` as a genuine «function» although nothing of the syntax has really been pre-parsed.)

At 1.4 fetching the expression up to final semi-colon is done using `\XINT_expr_fetch_to_semicolon`, hence semi-colons arising in the syntax do not need to be hidden inside braces.

11.29.1	<code>\xintdeffunc</code> , <code>\xintdefiifunc</code> , <code>\xintdeffloatfunc</code>	392
11.29.2	<code>\xintdefufunc</code> , <code>\xintdefiifunc</code> , <code>\xintdeffloatufunc</code>	395
11.29.3	<code>\xintunassignexprfunc</code> , <code>\xintunassigniifunc</code> , <code>\xintunassignfloatexprfunc</code>	396
11.29.4	<code>\xintNewFunction</code>	396
11.29.5	Mysterious stuff	398
11.29.6	<code>\XINT_expr_redefinemacros</code>	409
11.29.7	<code>\xintNewExpr</code> , <code>\xintNewIExpr</code> , <code>\xintNewFloatExpr</code> , <code>\xintNewIIExpr</code>	410
11.29.8	<code>\ifxintexprsafeatcodes</code> , <code>\xintexprSafeCatcodes</code> , <code>\xintexprRestoreCatcodes</code>	412

11.29.1 `\xintdeffunc`, `\xintdefiifunc`, `\xintdeffloatfunc`

1.2c (2015/11/12).

Note: it is possible to have same name assigned both to a variable and a function: things such as `add(f(f), f=1..10)` are possible.

1.2c (2015/11/13).

Function names first expanded then detokenized and cleaned of spaces.

1.2e (2015/11/21).

No `\detokenize` anymore on the function names. And `#1(#2)#3=#4` parameter pattern to avoid to have to worry if a `:` is there and it is active.

1.2f (2016/02/22).

La macro associée à la fonction ne débute plus par un `\romannumeral`, car de toute façon elle est pour emploi dans `\csname..\endcsname`.

1.2f (2016/03/08).

Comma separated expressions allowed (formerly this required using parenthesis `\xintdeffunc foo(x,...):=(..., ..., ...);`

1.3c (2018/06/17).

Usage of `\xintexprSafeCatcodes` to be compatible with an active semi-colon at time of use; the colon was not a problem (see #3) already.

1.3e (??).

`\xintdefefunc` variant added for functions which will expand completely if used with numeric arguments in other function definitions. They can't be used for recursive definitions.

1.4 (2020/01/10).

Multi-letter variables can be used (with no prior declaration)

1.4 (2020/01/11).

The new internal data model has caused many worries initially (such as whether to allow functions with «ople» outputs in contrast to «numbers» or «nuptles») but in the end all is simpler again and the refactoring of ? and ?? in function definitions allows to fuse inert functions (allowing recursive definitions) and expanding functions (expanding completely if with numeric arguments) into a single entity.

Thus the 1.3e `\xintdefefunc`, `\xintdefielfunc`, `\xintdeffloatfunc` constructors of «expanding» functions are kept only as aliases of legacy `\xintdeffunc` et al. and deprecated.

A special situation is with functions of no variables. In that case it will be handled as an inert entity, else they would not be different from variables.

11.29.4 *\xintNewFunction*

1.2h (2016/11/20). Syntax is *\xintNewFunction{<name>}[nb of arguments]{expression with #1, #2,... as in *\xintNewExpr*}*. This defines a function for all three parsers but the expression pars-

ing is delayed until function execution. Hence the expression admits all constructs, contrarily to `\xintNewExpr` or `\xintdeffunc`.

As the letters used for variables in `\xintdeffunc`, #1, #2, etc... can not stand for non numeric «oples», because at time of function call $f(a, b, c, \dots)$ how to decide if #1 stands for a or a, b etc... ? Of course «a» can be packed and thus the macro function can handle #1 as a «tuple» and for this be defined with the * unpacking operator being applied to it.

```

11.29.5 Mysterious stuff

There was an `\xintNewExpr` already in 1.07 from May 2013, which was modified in September 2013 to work with the `#` macro parameter character, and then refactored into a more powerful version in June 2014 for 1.1 release of 2014/10/28.

It is always too soon to try to comment and explain. In brief, this attempts to hack into the *purely numeric* `\xintexpr` parsers to transform them into *symbolic* parsers, allowing to do once and for all the parsing job and inherit a gigantic nested macro. Originally only f-expandable nesting. The initial motivation was that the `\csname` encapsulation impacted the string pool memory. Later this work proved to be the basis to provide support for implementing user-defined functions and it is now its main purpose.

Deep refactorings happened at 1.3 and 1.4.

At 1.3 the crucial idea of the «hook» macros was introduced, reducing considerably the preparatory work done by `\xintNewExpr`.

At 1.4 further considerable simplifications happened, and it is possible that the author currently does at long last understand the code!

The 1.3 code had serious complications with trying to identify would-be «list» arguments, distinguishing them from «single» arguments (things like parsing `#2+[[#1..[#3]..#4][#5:#6]]*#7` and convert it to a single nested f-exandable macro...)

The conversion at 1.4 is both more powerful and simpler, due in part to the new storage model which from `\csname` encapsulated comma separated values up to 1.3f became simply a braced list of braced values, and also crucially due to the possibilities opened up by usage of `\expanded` primitive.

```

Attention here that user function names may contain digits, so we don't use a \detokenize or ~

approach.

This syntax means that a function defined by \xintdeffunc never expands when used in another definition, so it can implement recursive definitions.

\XINT:NE:userefunc et al. added at 1.3e.

I added at \xintdefefunc, \xintdefiiefunc, \xintdeffloatefunc at 1.3e to on the contrary expand if possible (i.e. if used only with numeric arguments) in another definition.

The \XINTusefunc uses \expanded. Its ancestor \xintExpandArgs (*xinttools* 1.3) had some more primitive f-expansion technique.

11.29.6 \XINT_expr_redefinemacros

Completely refactored at 1.3.

Again refactored at 1.4. The availability of \expanded allows more powerful mechanisms and more importantly I better thought out the root problems caused by the handling of list operations in this context and this helped simplify considerably the code.

```

11.29.7 *\xintNewExpr*, *\xintNewIExpr*, *\xintNewFloatExpr*, *\xintNewIIExpr*

1.2c modifications to accomodate *\XINT_expr_deffunc_newexpr* etc..

1.2f adds token *\XINT_newexpr_clean* to be able to have a different *\XINT_newfunc_clean*.

As *\XINT_NewExpr* always execute *\XINT_expr_redefineprints* since 1.3e whether with *\xintNewExpr* or *\XINT_NewFunc*, it has been moved from argument to hardcoded in replacement text.

NO MORE *\XINT_expr_redefineprints* at 1.4 ! This allows better support for *\xinteval*, *\xinttheexpr* as sub-entities inside an *\xintNewExpr*. And the «cleaning» will remove the new *\XINTfstop* (detokenized from *\meaning* output), to maintain backwards compatibility with former behaviour that created macros expand to explicit digits and not an encapsulated result.

The #2#3 in clean stands for *\noexpand\XINTfstop* (where the actual *scantoken*-ized input uses \$ originally with catcode letter as the escape character).

```

4047 \def\xintNewExpr      {\XINT_NewExpr\xint_firstofone\xintexpr      \XINT_newexpr_clean}%
4048 \def\xintNewFloatExpr{\XINT_NewExpr\xint_firstofone\xintfloatexpr\XINT_newexpr_clean}%
4049 \def\xintNewIExpr     {\XINT_NewExpr\xint_firstofone\xintiexpr     \XINT_newexpr_clean}%

4052 \def\XINT_newexpr_clean #1>#2#3{\noexpand\expanded\noexpand\xintNEprinthook}%
4053 \def\xintNEprinthook#1.#2{\expanded{\unexpanded{#1.}{#2}}}%

```

1.2c for *\xintdeffunc*, *\xintdefiifunc*, *\xintdeffloatfunc*.

At 1.3, *NewFunc* does not use anymore a comma delimited pattern for the arguments to the macro being defined.

At 1.4 we use *\xintthebareeval*, whose meaning now does not mean unlock from csname but *firstofone* to remove a level of braces This is involved in functioning of *expr:userfunc* and *expr:userefunc*

```

4054 \def\XINT_NewFunc      {\XINT_NewExpr\xint_gobble_i\xintthebareeval\XINT_newfunc_clean}%
4055 \def\XINT_NewFloatFunc{\XINT_NewExpr\xint_gobble_i\xintthebarefloateval\XINT_newfunc_clean}%
4056 \def\XINT_NewIIFunc   {\XINT_NewExpr\xint_gobble_i\xintthebareiieval\XINT_newfunc_clean}%
4057 \def\XINT_newfunc_clean #1>{}%

```

1.2c adds optional logging. For this needed to pass to *_NewExpr_a* the macro name as parameter.

Up to and including 1.2c the definition was global. Starting with 1.2d it is done locally.

Modified at 1.3c so that *\XINT_NewFunc* et al. do not execute the *\xintexprSafeCatcodes*, as it is now already done earlier by *\xintdeffunc*.

4076 }%

```

1.2d's *\xintNewExpr* makes a local definition. In earlier releases, the definition was global.
\the\toks0 inserts the *\endgroup*, but this will happen after *\XINT_tmpa* has already been expanded...

The %1 is *\xint_firstofone* for *\xintNewExpr*, *\xint_gobble_i* for *\xintdeffunc*.

Attention that at 1.4, there might be entire sub-xintexpressions embedded in detokenized form. They are re-tokenized and the main thing is that the parser should not mis-interpret catcode 11 characters as starting variable names. As some macros use : in their names, the retokenization must be done with : having catcode 11. To not break embedded non-evaluated sub-expressions, the *\XINT_expr_getop* was extended to intercept the : (alternative would have been to never inject any macro with : in its name... too late now). On the other hand the ! is not used in the macro names potentially kept as is non expanded by the *\xintNewExpr*/*\xintdeffunc* process; it can thus be retokenized with catcode 12. But the «hooks» of *seq()*, *iter()*, etc... if deciding they can't evaluate immediately will inject a full sub-expression (possibly arbitrarily complicated) and append to it for its delayed expansion a catcode 11 ! character (as well as possibly catcode 3 ~ and ? and catcode 11 caret ^ and even catcode 7 &). The macros *\XINT_expr_tilde* etc... below serve for this injection (there are *two* successive *\scantokens* using different catcode regimes and these macros remain detokenized during the first pass!) and as consequence the final meaning may have characters such as ! or and special catcodes depending on where they are located. It may thus not be possible to (easily) retokenize the meaning as printed in the log file if *\xintverbosetrue* was issued.

If a defined function is used in another expression it would thus break things if its meaning was included pre-expanded ; a mechanism exists which keeps only the name of the macro associated to the function (this name may contain digits by the way), when the macro can not be immediately fully expanded. Thus its meaning (with its possibly funny catcodes) is not exposed. And this gives opportunity to pre-expand its arguments before actually expanding the macro.

12.19	Let the functions be known to the <code>\xintexpr</code> parser	431

Comments under reconstruction.

The original was done in January 15 and 16, 2019. It provided `asin()` and `acos()` based on a Newton algorithm approach. Then during March 25–31 I revisited the code, adding more inverse trigonometrical functions (with a modified algorithm, quintically convergent), extending the precision range (so that the package reacts to the `\xintDigits` value at time of load, or reload), and replaced high level range reduction by some optimized lower level coding.

This led me next to improve upon the innards of `\xintdefefunc` and `\xintNewExpr`, and to add to `xintexpr` the `\xintdefefunc` macro (see user documentation).

Finally on April 5, 2019 I pushed further the idea of the algorithm for the arcsine function. The cost is at least the one of a combined `sin()`/`cos()` evaluation, surely this is not best approach for low precision, but I like the principle and its suitability to go into hundreds of digits if desired.

Almost all of the code remains written at high level, and in particular it is not easily feasible from this interface to execute computations with guard digits. Expect the last one or two digits to be systematically off.

Also, small floating-point inputs are handled quite sub-optimally both for the direct and inverse functions; substantial gains are possible. I added the `ilog10()` function too late to consider using it here with the high level interface.

12.1 Catcodes, ε - \TeX and reload detection

12.5 Auxiliary variables (only temporarily needed, but left free to re-use)

These variables don't have really private names but this does not matter because only their actual values will be stored in the functions defined next. Nevertheless they are not unassigned, and are left free to use as is.

12.5.1 twoPi, threePiover2, Pi, Piover2

We take them with 60 digits and force conversion to *\xintDigits* setting via "0 + " syntax.

```
55 \xintdeffloatvar twoPi      := 0 +
56   6.28318530717958647692528676655900576839433879875021164194989;%
57 \xintdeffloatvar threePiover2 := 0 +

```

12.5.3 Inverse factorial coefficients: invfact2, ..., invfact44

Pre-compute 1/n! for n = 2, ..., 44

The following example (among many, see below) shows that we must be careful when pre-computing the 1/i!.

Consider $35!=1033314796638614492966651337523200000000$.
With *\xintDigit:=26*; *\xintfloateval{35!}* obtains 1.033314796638614492966651e40 which is the correct rounding to 26 digits. But *\xintfloateval{1/35!}* obtains 9.6775929586318909920898167e-41 which differs by 3ulp from the correct rounding of 1/35! to 26 places which is 9.6775929586318909920898164e-41. The problem isn't in the factorial computations, but in the fact that the rounding of the inverse of a quantity which is itself a rounding is not necessarily the rounding of the exact inverse of the original.

Here is a little program to explore this phenomenon systematically:

```
\xintDigits:=55;%
\edef\tempNlist{\xintSeq{2}{39}}
\xintFor* #1in{\tempNlist}\do{%
  we precompute some rounding here to }
```

```
% speed up things in the next double loop.
\expandafter\edef\csname invfact#1\endcsname {\xintfloatexpr 1/#1!\relax}%
}%
\xintFor*#1in{\xintSeq{4}{50}}\do{%
  \xintDigits:=#1;%
  \xintFor*#2in{\tempNlist}\do{%
    (D=#1, N=#2)
    % attention to != which is parsed as negation operator != followed by = (sigh...)
    \xintifboolfloatexpr{(1/#2!)!=0+\csname invfact#2\endcsname}%
      {ok}
      {mismatch: \xintfloateval{1/#2!} vs (exact)
       \xintfloateval{0+\csname invfact#2\endcsname}}%
  \par
}%
}%
}
```

We can see that for D=16, the problem is there with N=22, 25, 26, 27, 28...and more. If we were to use 1/i! directly in the \xintdeffloatfunc of sin_aux(X) and cos_aux(X) we would have this problem.

If we use \xintexpr1/i!\relax encapsulation in the function declaration the rounding will be delayed to actual use of the function... which is bad, so we need it to happen now. We could use (0+\xintexpr1/i!\relax) inside the declaration of the sine and cosine series, which will give the expected result but for readability we use some temporary variables. We could use seq(0+\xintexpr1/i!\relax, i = 2..44) but opt for an rseq. The semi-colon must be braced to hide it from \xintdeffloatvar grabbing of the delimited argument.

1.4 update: use \xintfloatexpr with optional argument for the rounding rather than «0+x» method.

```
67 \xintdeffloatvar invfact\xintListWithSep{, invfact}{\xintSeq{2}{44}}%
68     := \xintfloatexpr [\XINTdigits] % force float rounding after exact evaluations
69         \xintexpr rseq(1/2{;}@/i, i=3..44)\relax % need to hide inner ; from \xintdeffloatvar
70     \relax;%
```

12.6 The sine and cosine series

12.6.1 sin_aux(), cos_aux()

Should I rather use successive divisions by $(2n+1)(2n)$, or rather multiplication by their precomputed inverses, in a modified Horner scheme ? The \ifnum tests are executed at time of definition.

Criteria for truncated series using $\pi/4$, actually 0.79.

Small values of the variable X are very badly handled here because a much shorter truncation of the sine series should be used.

```
71 \xintdeffloatfunc sin_aux(X) := 1 - X(invfact3 - X(invfact5
72 \ifnum\XINTdigits>4
73             - X(invfact7
74 \ifnum\XINTdigits>6
75             - X(invfact9
76 \ifnum\XINTdigits>8
77             - X(invfact11
78 \ifnum\XINTdigits>10
79             - X(invfact13
80 \ifnum\XINTdigits>13
81             - X(invfact15
82 \ifnum\XINTdigits>15
83             - X(invfact17
```

```

84 \ifnum\XINTdigits>18           - X(invfact19
85
86 \ifnum\XINTdigits>21           - X(invfact21
87
88 \ifnum\XINTdigits>24           - X(invfact23
89
90 \ifnum\XINTdigits>27           - X(invfact25
91
92 \ifnum\XINTdigits>30           - X(invfact27
93
94 \ifnum\XINTdigits>33           - X(invfact29
95
96 \ifnum\XINTdigits>36           - X(invfact31
97
98 \ifnum\XINTdigits>39           - X(invfact33
99
100 \ifnum\XINTdigits>43          - X(invfact35
101
102 \ifnum\XINTdigits>46          - X(invfact37
103
104 \ifnum\XINTdigits>49          - X(invfact39
105
106 \ifnum\XINTdigits>53          - X(invfact41
107
108 \ifnum\XINTdigits>59          - X(invfact43
109
110      )\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi);\%

```

Criteria on basis of $\pi/4$, we actually used 0.79 to choose the transition values and this makes them a bit less favourable at 24, 26, 29...and some more probably. Again this is very bad for small X .

```

111 \xintdeffloatfunc cos_aux(X) := 1 - X(invfact2 - X(invfact4
112 \ifnum\XINTdigits>3           - X(invfact6
113
114 \ifnum\XINTdigits>5           - X(invfact8
115
116 \ifnum\XINTdigits>7           - X(invfact10
117
118 \ifnum\XINTdigits>9           - X(invfact12
119
120 \ifnum\XINTdigits>12          - X(invfact14
121
122 \ifnum\XINTdigits>14          - X(invfact16
123
124 \ifnum\XINTdigits>17          - X(invfact18
125
126 \ifnum\XINTdigits>20          - X(invfact20
127
128 \ifnum\XINTdigits>23          - X(invfact22
129
130 \ifnum\XINTdigits>25          - X(invfact24
131

```

```

132 \ifnum\XINTdigits>28
133     - X(invfact26
134 \ifnum\XINTdigits>32
135     - X(invfact28
136 \ifnum\XINTdigits>35
137     - X(invfact30
138 \ifnum\XINTdigits>38
139     - X(invfact32
140 \ifnum\XINTdigits>41
141     - X(invfact34
142 \ifnum\XINTdigits>44
143     - X(invfact36
144 \ifnum\XINTdigits>48
145     - X(invfact38
146 \ifnum\XINTdigits>51
147     - X(invfact40
148 \ifnum\XINTdigits>55

150 \ifnum\XINTdigits>58
151     - X(invfact44
152     )\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi)\fi);\%

```

12.6.2 Make `sin_aux()` and `cos_aux()` known to `\xintexpr`

We need them shortly for the `asin()` in an `\xintexpr` variant. We short-circuit the high level interface as it will not be needed to add some `\xintFloat` wrapper.

```

153 \expandafter\let\csname XINT_expr_func_sin_aux\expandafter\endcsname
154             \csname XINT_flexpr_func_sin_aux\endcsname
155 \expandafter\let\csname XINT_expr_func_cos_aux\expandafter\endcsname
156             \csname XINT_flexpr_func_cos_aux\endcsname

```

12.6.3 `sin_()`, `cos_()`

Use this only between $-\pi/4$ and $\pi/4$

```
157 \xintdeffloatfunc sin_(x) := x * sin_aux(sqr(x));%
```

Use this only between $-\pi/4$ and $\pi/4$

```
158 \xintdeffloatfunc cos_(x) := cos_aux(sqr(x));%
```

12.7 Range reduction for sine and cosine using degrees

Notice that even when handling radians it is much better to convert to degrees and then do range reduction there, because this can be done in the fixed point sense. I lost 1h puzzled about some mismatch of my results with those of Maple (at 16 digits) near $-\pi$. Turns out that Maple probably adds π in the floating point sense causing catastrophic loss of digits when one is near $-\pi$. On the other hand my `sin(x)` function will first convert to degrees then add 180 without any loss of floating point precision, even for a result near zero, then convert back to radians and use the sine series.

12.7.1 Core level macro \XINT_mod_ccclx_i

input: $\the\numexpr\XINT_mod_ccclx_i$ k.N. (delimited by dots)
 output: (N times 10^k) modulo 360. (with a final dot)
 Attention N must be non-negative (I could make it accept negative but the fact that *numexpr* / is not periodical in numerator adds overhead).

360 divides 9000 hence 10^{k} is 280 for k at least 3 and the additive group generated by it modulo 360 is the set of multiples of 40.

```
159 \def\XINT_mod_ccclx_i #1.% input <k>.<N>. k is a non-negative exponent
160 {%
161   \expandafter\XINT_mod_ccclx_e\the\numexpr

```

#2 will be empty in the "integer branch". Notice that a single dot "." is valid as input to the *xintfrac* macros. During developing phase I did many silly mistakes due to wanting to use too low-level interface, e.g. I would use something like #2[-\XINTdigits] with #2 the fractional digits, but there maybe some leading zero and then *xintfrac.sty* will think the whole thing is zero due to the requirements of my own core format A[N]....

Multiplication is done exactly but anyway currently float multiplication goes via exact multiplication after rounding arguments ; as here integer part has at most three digits, doing exact multiplication will prove not only more accurate but probably faster.

12.13 Core routine for inverse trigonometry

Compute $\arcsin(x)$

The approach I shall first describe (which is only a first step towards our final approach) converges quintically but requires an initial square root computation. For $\text{atan}(x)$, we do not have to do any such square root extraction. See code next.

The algorithm (for this first approach): we have $0 \leq t < 0.72$, let $t_1 = t * (1 + t^2 / 6)$. We also have $u = \sqrt{1 - t^2}$. We seek $a = \arcsin t$ with $t = \sin(a)$.

Then $t1 < \text{Arcsin } t$ and the difference (we don't know it!) δ_1 is < 0.02 . We compute $D = t * \cos(t1) - u * \sin(t1)$. This computation is done "exactly" via the `\xintexpr` encapsulation. In other terms we use doubled precision. Anyhow, currently (1.3e) the `Float` macros of `xintfrac.sty` for multiplication do go via such exact multiplication when the mantissas have the expected sizes. So we can't gain but only lose due to catastrophic subtraction in using float operations here.

Thus D is $\sin(a-t_1) = \sin(\delta_1)$. And $\delta_1 = \text{Arcsin } D$, but D is small! We then use again two terms of the Arcsin series and define $t_2 = t_1 + D * (1 + D^2/6)$. Let $\delta_2 = a - t_2$. Then δ_2 is of the order of the neglected term $3 * (\delta_1)^5/40$.

©copyright J.F. Burnol, March 30, 2019. This surely has a name.

The algorithm is quintically convergent. One can do the same to go from exp to log. Basically the idea is that we can improve the Newton Method for any function f for which knowing target value of f implies one also knows target value of its derivative. In fact I obtained the quintic algorithm by combining the Newton formula with the one from using $f(x)/f'(a)$ and not $f(x)/f'(x)$ in the update to cancel the two quadratic errors.

One iteration (t_2) gives about 9 digits, two iterations (t_3) 49 digits ! And if we want hepta-convergence we only need to use one more term of the Arcsin series in the update of the t_n ... really this is very nice.

And actually (t2) already gives 30 digits of floating point precision for input $t < 0.1$. Let's confirm this:

Each iteration costs a computation of one cos and one sine done at the full final precision. This is stupid because we should compute at an evolving precision, but anyhow this is not our problem

anymore as our final algorithm is not a loop but it does exactly one iteration for all inputs. As exemplified above it remains true that we could improve its speed for small inputs by using shorter auxiliary series (see below).

In January I used a loop via an `iter()` construct, with some `subs()` to avoid repeating computations. This can only be done in an `\xintNewFunction`. Here is how it looked after some optimization for the stopping criteria, after replacing generic Newton algorithm by a specific quintic one for arcsine:

```
\begingroup
\edef\x{\endgroup
\noexpand\xintNewFunction{asin_l}[2]{
    iter##1*(1+sqr##1)/6);
% FIXME : réfléchir au critère d'arrêt.
%
% Je n'utilise pas abs(D) pour un micro-gain est-ce que le risque en vaut la
% chandelle ? (avec abs(D) on pourrait utiliser la fonction avec un #1 négatif)
%
% Am I sure rounding errors could not cause neverending loop?
% Such things should be done with increased precision and rounded at end.
    subs((D<\ifcase\numexpr2+\XINTdigits-5*(\XINTdigits/5)\relax
          3.68\or2.32\or1.47\or0.923\or0.582\fi
          e-\the\numexpr\XINTdigits/5\relax)
    ?{break(@+D*(1+sqr(D)/6))}{@+D*(1+sqr(D)/6)},
    D=\noexpand\xintexpr
        subs##1*cos_aux(X) - ##2*@*sin_aux(X), X=sqr(@))
        \relax
    ),
    i=1++)dummy iteration index, not used but needed by iter()
}}\x
```

I don't have time to explain the final algorithm below and how the transition values were chosen or why (the series below is enough up to 59 digits of precision). It does only one iteration, in all cases. Using it for arcsine requires a preliminary square root extraction, but for arctangent one arranges things to avoid having to compute a square root.

©copyright J.F. Burnol, April 5, 2019. This surely has a name.

Certainly I can do similar things to compute logarithms.

```
424 \xintdeffloatfunc asin_aux(X) := 1

```

12.14 asin(), asind()

Only non-negative arguments t and u for asin_a(t,u), and asind_a(t,u).

At 1.4 usage of `sqrt_()` which has only one argument, whereas currently `sqrt()` admits a second optional argument hence sub-optimality here if we use `sqrt()`, especially since 1.4 handles more fully such functions with optional argument in `\xintdeffunc`.

Actually thinking of making `sqrt()` a one argument only function and `sqrt_()` will be the one with two arguments. But I worked hard on the `\xintdeffunc` hooks, thus some reticence, because why then not do that for all others?

```
443 \xintdeffloatfunc asin_a(t, u) := (t<u)?

12.16 atan(), atand()

This involves no square root!

TeX hackers note 1:

The `subs(, x = ...)` mechanism has no utility in a function definition, there is no parallel mechanism at the underlying macros, so in fact the substituted things will remain unevaluated if they involve indeterminates, so this is exactly like not trying to make things more efficient at all.

Currently, the only way is thus to employ auxiliary functions like is done next. Contrarily to TeX macros, we must define the functions one after the other in the correct order, so the auxiliaries come first.

TeX hackers note 2:

At 1.4, the way to inject lazy conditionals in function definitions has changed. Prior one used `if(,,)` and `ifsgn(,,,)` which was counter-intuitive because in pure numeric context they evaluate all branches. Now one must use `?` and `??` which are the lazy conditionals from the numeric context.

```

12.18 Synonyms: `tg()`, `cotg()`

These are my childhood notations and I am attached to them. In radians only. We skip some overhead here by using a `\let` at core level.

```

537 \expandafter\let\csname XINT_fexpr_func_tg\expandafter\endcsname
538                               \csname XINT_fexpr_func_tan\endcsname
539 \expandafter\let\csname XINT_fexpr_func_cotg\expandafter\endcsname
540                               \csname XINT_fexpr_func_cot\endcsname

```

12.19 Let the functions be known to the \xintexpr parser

See *xint.pdf* for some explanations (as well as code comments in *xintexpr.sty*). In fact it is this context which led to my addition at 1.3e of `\xintdefefunc` to the `\xintexpr` syntax.

```

541 \xintFor #1 in {sin, cos, tan, sec, csc, cot,
542           asin, acos, atan}\do
543 {%
544   \xintdefefunc #1(x) := \xintfloatexpr #1(sfloat(x))\relax;%
545   \xintdefefunc #1d(x):= \xintfloatexpr #1d(sfloat(x))\relax;%
546 }%
547 \xintFor #1 in {Arg, pArg, atan2}\do
548 {%
549   \xintdefefunc #1(x, y) := \xintfloatexpr #1(sfloat(x), sfloat(y))\relax;%
550   \xintdefefunc #1d(x, y):= \xintfloatexpr #1d(sfloat(x), sfloat(y))\relax;%
551 }%
552 \xintdefefunc tg(x) := \xintfloatexpr tg(sfloat(x))\relax;%
553 \xintdefefunc cotg(x):= \xintfloatexpr cotg(sfloat(x))\relax;%
554 \xintdefefunc sinc(x):= \xintfloatexpr sinc(sfloat(x))\relax;%

```

Restore used dummy variables to their status prior to the package reloading. On first loading this is not needed naturally, because this is done immediately at end of *xintexpr.sty*.

```
555 \xintFor* #1 in {iDTVtuwxyzX}\do{\xintrestorevariable{#1}}%
```

13 Package *xintlog* implementation

Contents

13.1	Catcodes, ε - \TeX and reload detection	432
13.2	Library identification	433
13.3	Loading of <i>poormanlog</i> package	433
13.4	The <i>log10()</i> and <i>pow10()</i> functions	433
13.5	The <i>log()</i> , <i>exp()</i> , and <i>pow()</i> functions	434
13.6	<i>\poormanloghack</i>	435

I almost included extended precision implementation for 1.3e but was a bit short on time; besides I hesitated between using *poormanlog* at starting point or not. For up to 50 digits, it would help reduce considerably the needed series for the logarithm. For more digits I should rather apply my copyrighted method of the arcsine (it must be in literature).

13.1 Catcodes, ε - \TeX and reload detection

```

46 \z%

```

Attention to catcode regime when loading below *poormanlog*. It (v0.04) uses `^` with its normal catcode but `\XINT_setcatcodes` would set it to letter.

This file can only be loaded from *xintexpr.sty* and it restores catcodes near its end. To play it safe and be hopefully immune to whatever is done in *poormanlog* or in *xinttrig.sty* which is loaded before, we will switch to standard catcode regime here.

As I learned the hard way (I never use my user macros), at the worst moment when wrapping up the final things for 1.3e release, `\xintexprSafeCatcodes` MUST be followed by some `\xintexprRestoreCatcodes` quickly, else next time it is used (for example by `\xintdefvar`) the `\xintexprRestoreCatcodes` will restore an obsolete catcode regime...

13.2 Library identification

```

47 \xintexprSafeCatcodes\catcode`_ 11
48 \XINT_providespackage
49 \ProvidesPackage{xintlog}%
50 [2020/02/19 v1.4a Logarithms and exponentials for xintexpr (JFB)]%

```

13.3 Loading of *poormanlog* package

Attention to catcode regime when loading *poormanlog*. It matters less now for 1.3f as those chunks of code from *poormanlog.tex* v0.04 which needed specific *xintexpr* like catcodes got transferred here anyway.

```

51 \ifdef{\RequirePackage}
52   \RequirePackage{poormanlog}%
53 \else
54   \input poormanlog.tex
55 \fi

```

`\XINT_setcatcodes` switches to the standard catcode regime of *xint*.sty* files. And we need the *xintexpr* catcode for `!` too (cf `\XINT_expr_func_pow`)

See the remark above about importance of doing `\xintexprRestoreCatcodes` if `\xintexprSafeCatcodes` has been used...

```
56 \xintexprRestoreCatcodes\csname XINT_setcatcodes\endcsname\catcode`!\! 11
```

13.4 The `log10()` and `pow10()` functions

The support macros from *poormanlog* v0.04 `\PoorManLogBaseTen`, `\PoorManLogPowerOfTen`, `\PoorManPower` got transferred into *xintfrac.sty* at 1.3f.

```

57 \expandafter\def\csname XINT_expr_func_log10\endcsname#1#2#3%
58 {%

```

```

59      \expandafter #1\expandafter #2\expandafter{%
60      \romannumeral`&&@\XINT:NHook:f:one:from:one
61      {\romannumeral`&&@\PoorManLogBaseTen#3}}%
62 }%
63 \expandafter\let\csname XINT_expr_func_log10\expandafter\endcsname
64             \csname XINT_expr_func_log10\endcsname
65 \expandafter\def\csname XINT_expr_func_pow10\endcsname#1#2#3%
66 {%
67      \expandafter #1\expandafter #2\expandafter{%
68      \romannumeral`&&@\XINT:NHook:f:one:from:one
69      {\romannumeral`&&@\PoorManPowerOfTen#3}}%
70 }%
71 \expandafter\let\csname XINT_expr_func_pow10\expandafter\endcsname
72             \csname XINT_expr_func_pow10\endcsname

```

13.5 The `log()`, `exp()`, and `pow()` functions

The `log10()` and `pow10()` were defined by `poormanlog v0.04` but have been moved here at `xint 1.3f`. The support macros are defined in `xintfrac.sty`.

```

73 \def\XINT_expr_func_log #1#2#3%
74 {%
